PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tra Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The numbe and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

7974 DISTRIBUTION OF GASTRIN CELLS IN THE GASTRIC MUCOSA: AN IMMUNOFLUORESCENCE STUDY. (Jpn.) Nagata, T. (Second Dept. Pathology, Kyushu Univ., Fukuoka 812, Japan). *Fukuoka Acta Med.* 68(7):313-326; 1977.

The morphology and distribution of gastrin cells in gastric mucosal surgical specimens from 27 patients with carcinoma, 13 with gastric ulcer, 19 with duodenal ulcer, and 4 with other lesions were examined, using an indirect immunofluorescence method. Synthetic human 1-17 gastrin antiserum was used. Gastrin cells were found almost exclusively in the mucous membrane of the pyloric antrum, and their distribution was patchy. They were most numerous in the foveolae at the level of the middle third of the mucosal layer. Smaller numbers of cells were observed in the pyloric glands, the foveolae of the fundic mucosa, and the Brunner's glands of the duodenal bulb. No gastrin cells were found in the fundic glands, the cardiac glands, or in intestinalized gastric mucosal epithelium. Gastrin cells were frequently oval in shape, and the immunofluorescence was entirely cytoplasmic and yellow-green in color with unstained nuclei. The cytoplasm was clear when stained with hematoxylin and eosin. The cells were argyrophilic but not argentaffin. The number of gastrin cells decreased with increasing age of the patient and with increased intestinal metaplasia and gastric mucosal atrophy. In cases without intestinal metaplasia, the number of gastrin cells in the gastric mucosa within 7 cm from the pyloric ring ranged from 200/cm to 250/cm; the number decreased gradually as the distance from the pyloric ring increased. There was no apparent relationship between the number of gastrin cells and gastric secretion.

7975 EVIDENCE OF INNERVATION OF THE SMALL INTESTINE FROM THE CERVICAL SYMPATHETIC GANGLIA. (Eng.) Ahlman, B. H.; Lundberg, J. M.; Dahlstrom, A.; Larsson, I.; Pettersson, G.; Kewenter, J.; *et al.* (Dept. Surgery III, Univ. Goteborg, Goteborg, Sweden). *J. Surg. Res.* 24(3):142-149; 1978.

To study further the possible nervous pathways from the sympathetic neck ganglia via the vagal nerves to the intestine of the cat, intraoperative nerve-crush procedures were combined with the fluorescence method of Hillarp-Falck to visualize monoamine-containing nerve fibers and with the horseradish peroxidase (HRP) technique to demonstrate neuronal pathways by retrograde mapping. Two normal cats and two in which the superior cervical ganglia (SCG) bilaterally had been surgically removed were subjected to crushing of the right vagal nerve at the cervical and subdiaphragmatic levels 30-45 min before this vagal tissue was dissected for examination by fluorescence microscopy. Four other cats were injected at several hundred 0.5-cm intervals around the circumference of the gut wall with HRP (0.5-1.0 g/animal). Unilateral (right) crush of the cervical vagus and the cervical sympathetic chain was performed immediately (cat I), 24 hr after the injections (cats II and III), or not at all (cat IV); the tissues were dissected for examination at 24, 60, 72 hr, or 5 days, resp., in cats I-IV. In the two normal cats with intact SCG, many fibers with accumulated fluorescent material were seen cranial to the crush at the cervical level, due to a proximodistal, intra-axonal transport of amine storage granules accumulating proximal to the crush site. At the subdiaphragmatic level, the vagal nerve contained a large number of fluorescent fibers cranial to the crush. Removal of the SCG caused a complete disappearance of the fluorescent fibers at the cervical level, but many fluorescent fibers still remained at the subdiaphragmatic level. In all the cats, the celiac mesenteric inferior ganglion contained many HRP-positive cells. No other region in cat I was HRP-positive. In cats II and III, a few HRP-positive cells were seen in the left nodose ganglion, left SCG, and left and right stellate ganglia. In cat IV, all examined ganglia contained (on both sides) either a few HRP-positive cells (in the thoracic, nodose, and superior cervical ganglia) or a moderate number of HRP-positive cells (in the stellate ganglia). The fluorescence studies demonstrate that in the cat the cervical vagus carries catecholamine (CA)-containing fibers, emanating from the SCG. The persistence of CA fibers at the subdiaphragmatic level demonstrates that the vagus nerve receives more CA fibers caudal to the cervical level, probably from the stellate, and possibly from the intrathoracic sympathetic ganglia. The results clearly demonstrate that not only the stellate ganglia but also the SCG via the vagus nerve send CA fibers that innervate part of the small intestine, strongly modifying the classical hypothesis that these ganglia innervate mainly the head, neck, and heart.

ABSORPTION - EXCRETION - TRANSPORT

7985 THE BILE DUCT LIGATED ANIMAL: A MODEL FOR DETERMINING TOTAL INTESTINAL ABSORPTION. (Eng.) Halladay, S. C.; Enderlin, F. E.; Parkinson, T. M.; Honohan, T. (Biological Sciences, Dynapol, 1454 Page Mill Rd., Palo Alto, CA 94034). *Drug Chem. Toxicol.* 1(2):203-218; 1978.

A new bile duct-ligated animal model for determining total intestinal absorption was evaluated using compounds with markedly different metabolism and excretion characteristics. The test solutions were administered p.o. by gavage in control and bile duct-ligated female Sprague-Dawley rats or ICR/Sim mice. A comparison of the serum concentration time curves for digoxin, bumetanide, imipramine, hexobarbital, and sodium benzoate in ligated and control rats indicated that bile duct ligation had no significant effect on absorption *per se* during the study period. In ligated rats, total absorption of imipramine (which undergoes enterohepatic circulation), as estimated from urine and tissue recoveries, was 92%. A significant overestimation of total absorption (128%) resulted from combining urine and tissue recoveries from controls with bile recoveries from cannulated rats. For sodium benzoate, which undergoes little or no enterohepatic circulation, there was no significant difference in total recoveries determined by these two methods (97% versus 101%). In ligated mice, absorption o imipramine and sodium benzoate was 80% and 89%, resp. This model simply and accurately estimates intestinal absorption of both types of compounds, and eliminates the error inherent in determining absorption of compounds that are excreted in the bile when urine, feces, and tissue data from one animal are combined with bile data from another. The bile duct-ligated animal model is applicable especially to small animals such as mice, in whic bile duct cannulation is extremely difficult, and to the study of compounds whose properties do not permit traditional methods to be used.

7986 EFFECT OF MODIFIED SHAM FEEDING ON JEJU TRANSPORT AND PANCREATIC AND BILIARY SECRETION IN MAN. (Eng.) Read, N. W.; Cooper, K.; Fordtran, J. S. (Univ. Texas Health Science Center, Dallas, TX 75235). *Am. J. Physiol.* 234 (4):E417-E420; 1978.

The effect of modified sham feeding (thoroughly masticating but not swallowing an appetizing meal on the intestinal transport of water and electrolytes was studied using jejunal perfusion via a triple-lumen tube to investigate whether intes-inal secretion is under parasympathetic control. en volunteers who had experienced intestinal perfusion previously and of whom three had pentagastrin-fast achlorhydria (controls for acid effect) were used in the 4-hr experiment (the 1st, rd, and 4th hr were control periods, the 2nd hr as the experimental sham feeding). Gastric perfusion was continuous; the infusion site was the uodenojejunal flexure, and the collecting site as the gastric antrum; measurements were performed o assure that no gastric acid entered the test egment. Sham feeding produced a significant ise ($p<0.01$) in gastric acid output in the seven ormal subjects compared with the achlorhydric ontrols. Movement of water and electrolytes cross the jejunal wall and the jejunal potential ifference made no significant response to sham eeding. There was no consistent change in the utput of amylase, protein, or bile acids in response to sham feeding in the normal or achlorydric subjects. The results suggest that cephlic stimulation of the vagus by itself does not nfluence jejunal transport, but the vagus may act n concert with other factors as a regulator of jeunal transport. The results also suggest that luctuation in bile acid secretion is not an imporant regulator of ion transport in the jejunum, at east in the basal state.

987 INTESTINAL ABSORPTION OF ASCORBIC ACID AND ITS PASSAGE THROUGH THE LIPOID MEMRANE OF GUINEA PIGS.

(Eng.) Odumosu, A.; Wilson, . W. M. (Dept. Pharmacology, Trinity Coll., ublin 2, Ireland). *Int. J. Vitam. Nutr. Res.* 48 1):3-11; 1978.

he intestinal absorption of ascorbic acid (AA) and ts passage through the lipoid membrane was studied n normal (N), hypervitaminoic (HV), and scorbutic S) guinea pigs. Measurements were made in ligated egments of the intestinal lumen of intact living ats. The animals received either a scorbutogenic iet alone (group S) or this diet plus 20 mg vitain C/day (in group N) or 100 mg vitamin C/day (in roup HV) for 27 days prior to the absorption study. lasma and WBC concentrations of AA were measured efore and after AA (20 mg in 1 ml) or saline (1 l) had been introduced into the intestinal loops here the solutions were then maintained for 2 hr. fter introduction of AA, small and insignificant levations in the WBC AA concentrations occurred n each group, and the plasma levels of AA rose rom 0.60 ± 0.3 to 0.96 ± 0.07 mg/ml ($p<0.02$) in he N group and from 1.14 ± 0.18 to 1.57 ± 0.17 g/ml ($p<0.05$) in the HV group, but only from 0.11 0.01 to 0.13 ± 0.09 mg/ml in the S group. When he retention of AA in the intestinal loops was easured following saline and AA treatments for 2 r, the largest amount of AA remained in the loops f the S group (8.38 mg/ml) compared with the N roup (2.9 mg/ml) and the HV group (3.85 mg/ml), he S group value being significantly different rom the other two ($p<0.02$). Mucosal cell uptake f AA was least in the HV group (3.68 mg/g weight), reater in the N group (7.12 mg/g), and greatest n the S group (10.13 mg/g), all differences being significant ($p<0.01$ or $p<0.05$). The muscle content of AA was highest in the S group after the introduction of AA (1.94 mg/g weight) compared with the N and the HV groups (1.75 mg/g in both). Preferential intestinal cell absorption of AA in the S guinea pigs was demonstrated: the AA uptake from the intestinal lumen and retention in the mucosal cells was greatest in this group, but impaired transfer of AA to the plasma also occurred. The S mucosal cells showed histological signs of damage, which may account for this negligible transfer of AA from the intestine into plasma. The high AA concentration in S mucosal cells may be due to a passive diffusion mechanism resulting from the relatively high concentration of AA in the intestinal lumen. It is possible that in acute scurvy, only passive transfer of AA occurs, while active transfer into the plasma is suppressed.

7988 ROLE OF SULFHYDRYL GROUPS IN ACID TRANSPORT BY STOMACH.

(Eng.) Fromm, D.; Fuhro, R. (Harvard Medical Sch., Boston, MA). *Surg. Forum* 28:351-353; 1977.

The effects of two sulfhydryl-reactive agents, *p*-chloromercuribenzene sulfonic acid (PCMBS) and dithiothreitol (DTT), on acid secretion and backward diffusion by isolated rabbit gastric mucosa were studied. The spontaneous acid secretory rate of fundic mucosa (2.0 ± 0.2 μEq/hr cm^2) was constant over 90 min. Addition of sulfhydryl-oxidizing PCMBS (0.5 mM) to the mucosal side significantly decreased the basal rate of acid secretion to 0.2 ± 0.1 μEq/hr/cm^2 ($p<0.001$), but its addition to the serosal side was without effect. Addition of sulfhydryl-reducing DTT (4 mM) to the mucosal side significantly stimulated acid secretion to 2.7 ± 0.3 μEq/hr/cm^2 ($p<0.001$) in both the absence and presence of PCMBS whose inhibitory effect DTT was able to prevent and reverse. Addition of 4 mM cysteine (another sulfhydryl-reducing agent) to the mucosal side did not stimulate acid secretion but did completely prevent inhibition by PCMBS. The presence of PCMBS increased the rate of luminal acid loss by the fundic mucosa (from 0.3 ± 0.1 to 1.3 ± 0.2 μEq/hr/cm^2, $p<0.001$) and decreased the rate of luminal acid loss by antral mucosa (from 1.0 ± 0.2 to 0.4 ± 0.1 μEq/hr/cm^2, $p<0.001$). DTT alone did not change luminal acid loss by the antrum; it reversed the PCMBS effect on luminal acid loss by the fundus. The mean difference between the mucosal and serosal rates of CO$_2$ appearance approximated the rate of acid secretion both before and after PCMBS exposure (2.8 ± 0.5 and 0.2 ± 0.1 μM/hr/cm^2, resp.) but responded to DTT by increasing significantly (from 2.2 ± 0.6 to 3.3 ± 0.6 μM/hr/cm^2, $p<0.025$), indicating that both agents primarily affect mineral rather than organic acid secretion. Both mucosal and serosal addition of PCMBS caused a 52-85% decrease in shortcircuit current ($p<0.001$) and a 15-35% increase in tissue electrical resistance of the fundus ($p<0.001$). DTT alone did not affect these parameters but did reverse the effects of PCMBS on them. It is concluded that the sulfhydryl sites associated with acid secretion are located on the luminal side of the mucosa, that they are separate from the sites associated with active transport of sodium and chloride, that the increase in backward diffusion caused by PCMBS is due to inhibition of acid secretion, and that the stimulatory effect of DTT alone is not due to the prevention of spontaneous oxidation of sulfhydryl groups.

7989 D-XYLOSE ABSORPTION TEST: PHARMACOKINETIC AND STATISTICAL STUDY.

(Fre.) Huguenin, P.; Cochet, B.; Balant, L.; Loizeau, E. (Hopital Cantonal, CH-1211 Geneve 4, Switzerland). *Schweiz. Med. Wochenschr.* 108(6):206-214; 1978.

D-xylose pharmacokinetics were studied in six healthy subjects by serial measurement of blood and urinary D-xylose levels following p.o. or i.v. administration of D-xylose. Four tests were used in these subjects: A--23 g D-xylose in 1,000 ml 0.45% NaCl, i.v., over 60 min; B--4.6 g D-xylose in 1,000 ml 0.45% NaCl, i.v., over 60 min; C--25 g D-xylose in 500 ml H_2O, p.o., over 5 min; and D--5 g D-xylose in 500 ml H_2O, p.o., over 5 min. NaCl (0.9%, 500 ml) was perfused over 60 min during tests C and D. A different order of the tests was used for each subject; there was a 1-week or 1-month interval between tests. In addition, 13 patients with obesity, renal, or hepatic insufficiency or a T-tube after cholecystectomy were also investigated. Following i.v. administration of D-xylose, there were individual variations in both the rate and completeness of D-xylose absorption, so that the time and value of peak D-xylose blood level were highly variable. The urinary elimination was about 50% of the administered dose and was nearly complete by 8 hr. After p.o. administration, the D-xylose blood levels rose rapidly over a roughly 2-hr period (there were significant increases, $p<0.01$ or $p<0.05$, in level during this early period) and then decreased semilogarithmically over the next 6 hr. The urinary elimination was about 30% for the 25-g dose and about 40% of the 5-g dose at 8 hr. Renal insufficiency increased the apparent elimination half-life of D-xylose and markedly reduced renal D-xylose excretion. The results indicate that there is a very wide range of blood and urinary levels obtained by the D-xylose tolerance test. Urinary D-xylose excretion alone is not a reliable index of intestinal absorption.

7990 INTESTINAL APOPROTEINS DURING FAT ABSORPTION.

(Eng.) Schonfeld, G.; Bell, E.; Alpers, D. H. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *J. Clin. Invest.* 61(6):1539-1550; 1978.

Apolipoprotein (Apo) A-I, ApoB, and ApoE (or arginine-rich apoprotein, ARP) were localized in rat intestinal mucosa by an indirect immunofluorescence method to compare their roles in the intracellular production of intestinal chylomicrons (and/or very low density lipoproteins, VLDL). In addition, tissue levels of ApoA-I and ApoB were measured by radioimmunoassay during fat absorption. Antisera were produced using ApoA-I isolated from rat plasma high-density lipoprotein, and ApoB and ARP from plasma VLDL by column chromatography. The apoproteins yielded single bands on polyacrylamide disc gel electrophoresis in urea and in sodium dodecyl sulfate. Anti-apoprotein antisera produced in rabbits appeared to be monospecific on double-antibody immunoprecipitation of ^{125}I-label apoproteins. In fasted animals, granular stainir of ApoA-I was noted in the Golgi regions of epithelial cells in the top third of the villus. At 30 min, when fat droplets were seen in the supran clear cytoplasm of the cells along the top two-thirds of the villus, intense ApoA-I staining surrounded the cytoplasmic droplets. Later, whe epithelial cells and lamina propria both contain fat droplets, bright ApoA-I stain surrounded many droplets in the supranuclear cytoplasm and in th lamina propria. Over the same period, ApoA-I ti sue levels rose 10-fold. The distribution and time-course of ApoB staining was nearly identica with that of ApoA-I. Concomitantly, tissue ApoB levels doubled. In contrast, in fasting rat intestine, ARP staining was sparse, punctate, and confined to the lower quarter of the villus. Af fat feeding, stained droplets were seen only in the lamina propria near the base of the villus, even though abundant ARP occurred in cells along most of this length of the villus. Stain never surrounded droplets inside cells. Thus, ApoA-I and ApoB appear to participate in the intracellu assembly of gut lipoproteins, whereas ARP does n although ARP was found within the mucosal cells. The liver stained heavily for ARP and lightly fo ApoA-I, whereas intestine stained heavily for Ap and lightly for ARP. Both organs stained for Ap These findings suggest that there may be some qu titative "specialization" of the two organs that secrete lipoproteins.

7991 ENTERAL ABSORPTION OF HIGH CALCIUM DOS AS DETERMINED BY MEANS OF STABLE ISOTO

(Ger.) Behne, D.; Bratter, P.; Herzfeld, U.; Kr D. (Bereich Kernchemie und Reaktor, Hahn-Meitne Institut fur Kernforschung Berlin, Glienicker St 100, D-1000 Berlin 39, W. Germany). *Klin. Woche schr.* 56(2):69-74; 1978.

The enteral resorption of high p.o. Ca doses (5 and 1,000 mg; calcium-Sandoz forte and calcium-Sandoz fortissimum, resp.) was determined in ei healthy subjects by use of a double-isotope met The isotopes were assayed by neutron activation analysis. The stable ^{48}Ca isotope was used to label the p.o. Ca dose. The rapidly exchangeab body Ca pool was measured by the i.v. administra tion of $CaCl_2$ enriched with the stable ^{46}Ca isotope immediately after p.o. administration of t p.o. Ca doses. The 24-hr Ca exchange, determin from the serum ^{46}Ca level, was found to be 6.4 1 g or 98.8 ± 15.4 mg/kg of body weight. For t p.o. administered Ca, the elimination constant was 0.980 for the 500-mg Ca dose, and 0.880 mg for the 1,000-mg dose. The invasion constant w 0.056 and 0.073, resp., for the two doses while the elimination half-life was 185 min for eithe dose. The resorption rate was 30.5% for 500 mg and 28% for 1,000 mg, i.e., the resorption rate was independent of the dose administered. The serum Ca level showed a short-term rise following the oral administration of 1,000 mg Ca. The findings indicate that the quantity of resorbed Ca is directly proportional to the p.o. dose at high doses and that high p.o. Ca doses can be used therapeutically in degenerative bone diseases.

MOTILITY

8005 THE EFFECTS OF PARAOESOPHAGEAL STRUCTURES AND VAGOTOMY ON THE CANINE LOWER OESOPHAGEAL SPHINCTER FUNCTION. (Eng.) Laitinen, S. (Univ. Central Hosp., SF-90220 Oulu 22, Finland). *Ann. Chir. Gynaecol.* 66(6):304-310; 1977.

The effects of extrinsic paraesophageal structures and of the vagus nerve on lower esophageal function were investigated in dogs. Manometry demonstrated a high-pressure zone at the gastroesophageal junction of all 25 dogs examined. In all dogs in which the gastroesophageal junction was isolated from surrounding structures by a stiff-walled Silastic tube, the mean resting lower esophageal sphincter pressure (LESP) decreased from a preoperative level of 14.0 ± 3.0 mm Hg to 13.0 ± 2.7 mm Hg. Transabdominal subdiaphragmatic vagotomy, transthoracic subhilar vagotomy, or cervical vagotomy did not significantly change the mean resting LES pressure, but the response to abdominal compression was significantly decreased ($p<0.01$) by all three procedures. The vagus nerves apparently have no major role in the maintenance of resting LESP. The LES response to increased intra-abdominal pressure seems to represent a genuine increase in LES tone, to which extrinsic mechanical factors add only a small contribution. This response seems to be mediated by a vagal reflex arc, the afferent part of which has its origin below the diaphragm.

8006 RELATION OF GASTROESOPHAGEAL SPHINCTER PRESSURE AND ESOPHAGEAL CONTRACTILE WAVES TO AGE IN MAN.

(Eng.) Csendes, A.; Guiraldes, E.; Bancalari, A.; Braghetto, I.; Ayala, M. (Hospital J. J. Aguirre, Santos Dumont 999, Santiago, Chile). *Scand. J. Gastroenterol.* 13(4):443-447; 1978.

To determine a normal range of values for gastroesophageal sphincter pressure (GESP) and peristaltic wave amplitude (PWA) and variations in these levels among subjects of different age groups, esophageal motility was studied in 113 normal subjects ranging in age from 2 months to 74 yr. The GESP levels were significantly higher in children aged 2-5 months (37.2 ± 3.8 mm Hg) than in all age groups over 1 yr of age ($p<0.001$). With increasing age, the resting GESP gradually fell to a mean of slightly over 12 mm Hg in age groups between 15 and 24 yr and between 55 and 64 yr. There was a further drop in subjects aged 65 to 74 yr. Children in the 6- to 12-month age group also had significantly higher ($p<0.01$) pressures than did all adult groups and children in the 6- to 14-yr age group, but not from children in the 1- to 5-yr age group. In the adult population, the lowest GESP recorded was 7 mm Hg and the highest 20 mm Hg. Sphincter length increased with age from 1.1 cm in the 2- to 5-month age group up to 2.4 cm in the 15- to 24-yr group. There was no further change thereafter. The PWA was similar in all age groups except those 65 yr or older; in the latter group, the percentage of peristaltic waves induced by deglutition was 75%, while that in all other groups ranged between 82% and 100%.

8007 THE ROLE OF LOCAL CHOLINERGIC PATHWAYS IN THE MOTOR RESPONSE TO CHOLECYSTOKININ AND GASTRIN IN ISOLATED GUINEA-PIG FUNDUS AND ANTRUM.

(Eng.) Gerner, T.; Haffner, J. F. W. (Ulleval Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 12(6):751-757; 1977.

Studies were carried out to determine to what extent the local cholinergic pathways participate in the motor response to cholecystokinin-pancreozymin (CCK-PZ) and gastrin in guinea pig fundus and antrum *in vitro*. The motor responses to acetylcholine and the ganglion-stimulating agent, dimethylphenylpiperazinium (DMPP), were studied for comparison. CCK-PZ (0.38 U/ml), gastrin (0.05 μg/ml), and acetylcholine (10^{-3} M) increased antral rhythmic activity and fundal basal pressure ($p<0.05$). DMPP (10^{-5} M) also generally increased antral rhythmic activity, but it invariably induced a drop in fundic pressure. The antral motor effects were significantly ($p<0.05$) blocked by 10^{-5} M atropine or 10^{-6} M tetrodotoxin. However, the fundal motor responses were almost completely unaffected. It is concluded that CCK-PZ and gastrin exert their antral motor effects essentially through local cholinergic neural pathways, while the motor responses in the fundus are almost entirely independent of these pathways.

8008 EFFECTS OF CERULEIN ON INTESTINAL MOTIL

(Jpn.) Nakamura, N.; Shiozaki, S.; Kojima, T.; Shimizu, M.; Tanaka, M. (Pharmaceutical Res. Lab., Kyowa Hakko Kogyo Co., Ltd., Shimotogari, Nagaizumicho, Shizuoka 411, Japan). *Folia Pharmacol. Jpn.* 73(7):743-756; 1977.

The effects of cerulein on intestinal motility were compared with those of neostigmine, pantethine, prostaglandin E_1 (PGE_1), and prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$). Cerulein stimulated electric discharges in the intestinal tracts of anesthetized rabbits and was more potent than either neostigmine or pantethine. The small intestine was more sensitive to this agent than was the large intestine. PGE_1 inhibited, while $PGF_{2\alpha}$ stimulated ele trical discharges in the small intestine. Atropi did not completely inhibit the stimulatory effect of cerulein. Cerulein promoted the transit of a charcoal meal through the intestine of the mouse and was approximately 30 times more potent than neostigmine. At high doses, the promotion was reduced, and, the reduction was inhibited by reserpine or phentolamine-propranolol. These observations indicate that cerulein produces a catecholamine release at high doses. Cerulein increased intestinal transit time in cecectomized mice at doses 30 times higher than given to intact mice. Cerulein, neostigmine, PGE_1, and PGF_2 produced an excitatory effect on the isolated rabbit intestine. The minimal effective concentration of these four substances were 3×10^{-10} to 1 10^{-8}, 10^{-9}, and 3×10^{-11} g/ml in the ileum and 3 10^{-9} to 10^{-8}, 10^{-8} to 3×10^{-8}, 10^{-10}, and 10^{-11} g/ml in the proximal colon, resp.

Stomach

8020 ULTRASTRUCTURAL CHANGES IN OXYNTIC CELLS ASSOCIATED WITH SECRETORY FUNCTION: A MEMBRANE-RECYCLING HYPOTHESIS. (Eng.) Forte, T. M.; Machen, T. E.; Forte, J. G. (Donner Lab., Univ. California, Berkeley, CA 94720). *Gastroenterology* 73(4, Part 2):941-955; 1977.

Changes in piglet oxyntic cells associated with secretory function were studied ultrastructurally after the induction of secretion by histamine and after removal of the secretagogue. Morphological changes consisting chiefly of proliferation of the secretory surface were detected in the piglet oxyntic cell as early as 3 min after the addition of 10^{-5} M histamine to the preparation and before the production of detectable amounts of HCl secretion. However, there were frank changes in electrophysiology indicative of secretion: mucosal resistance and potential difference decreased. Microfilaments in the resting state and in the early phases of the onset of HCl secretion formed a ring of parallel filaments just beneath the microvillar plasma membrane; during maximal secretion, there appeared to be some detachment of microfilaments, which then appeared condensed in the center of the elongated microvillar processes. During the early stages of secretagogue withdrawal, when microvilli were condensed, the microfilaments showed great disorganization. With reestablishment of the resting state, the microfilaments were again aligned parallel with the microvilli. Structural changes associated with the reestablishment of the resting state were striking. In general, the apical surface membrane was reorganized or recycled back into the cytoplasmic tubulovesicular form. Analysis of intervening structural events showed a complex series of membrane alterations, which were characterized as: (a) condensation of elongated apical microvilli within the canalicular space; (b) close apposition and association of secretory membrane surfaces; (c) massive endocytosis of surface membranes into the cytoplasm, frequently in the form of pentalaminar membrane structures; and (d) reappearance of tubulovesicle profiles within the cytoplasm. The endocytosed pentalaminar structures had a thickness (242 A) just double that of single plasma membranes (119 A), thus making it unlikely that they represent fused membranes. Still, the very close apposition and contact of these membrane surfaces suggest that critical physical changes underlie this phase of membrane uptake. Morphological events after the withdrawal of histamine suggest that there must be important controlling steps in the phase of massive membrane uptake and in the reformation of tubulovesicular structures.

8021 ADENYLATE CYCLASE OF HUMAN GASTRIC MUCOSA.

(Eng.) Simon, B.; Kather, H. (Medizinische Universitatsklinik Heidelberg, Bergheimerstrasse 58, D-6900 Heidelberg, W. Germany). *Digestion* 16(1/2):175-179; 1977.

Adenylate cyclase activity was studied in homogenates of human gastric mucosa, and the effects of histamine and catecholamines on this activity were examined. Stomach tissue was obtained by subtotal gastric resection from seven patients with peptic ulcer. The mean basal adenylate cyclase activity of the gastric mucosa averaged 0.85 ± 0.4 nmol cyclic AMP (cAMP) formed/mg protein/15 min. Saturating concentrations of histamine (5×10^{-3} M) caused an increase in enzyme activity of about fourfold. cAMP accumulation in the same preparation was enhanced approximately two- to threefold by maximally effective concentrations of epinephrine (5×10^{-4} M). The concentrations required for half maximal stimulation were 5×10^{-5} M for both activators. Isoproterenol stimulated the enzyme activity to about the same degree as did epinephrine. The stimulatory action of catecholamines and histamine were additive, indicating that these substances act on separate adenylate cyclases The histamine responsiveness of the enzyme system was almost completely abolished by 1×10^{-3} M cimetidine, and catecholamine excitation was selectively blocked by propranolol (1×10^{-5} M). The results show that human gastric mucosa contains at least two separate hormone-sensitive adenylate cyclases coupled to different receptors: one being responsive to histamine and the other to catecholamines. The demonstration of a histamine-sensitive adenylate cyclase system in human gastric mucosa is consistent with the concept that cAMP is the intracellular mediator of the secretagogue effect of histamine in man as well as in amphibia and rodents.

8022 CHLORIDE TRANSPORT AND ACID SECRETION IN STOMACH.

(Eng.) Durbin, R. P. (Cardiovascular Res. Inst., Univ. California San Francisco, San Francisco, CA 94143). *Gastroenterology* 73(4, Part 2):927-930; 1977.

Different approaches to identifying the cellular Cl^- pool to facilitate the localization of the several modes of Cl^- transport in isolated frog gastric mucosa are illustrated. Flux studies on the effects of stimulating acid secretion and of removing secretory Cl^- on movement of Cl^- from nutrient to secretory solution and on the effects of removing nutrient Cl^- on the movement of Cl^- from secretory to nutrient solution showed that only a few minutes were required for the isotopic flux to reach a steady state. Cellular Cl^- uptake was quantitated by determining the extracellular space, using ^3H-mannitol. The overall mannitol space of 54% did not differ significantly from that reported for the mannitol space in tied mucosal sacs and was fairly close to the inulin space of 47-52% quoted for mounted mucosae. Therefore, the mannitol space seems to be a reasonable estimate of the extracellular space. The large mannitol space of 47% labeled from the nutrient solution corresponded to the serosal layer of connective tissue prominent in histological sections. The total tissue Cl^- (56.1 mEq/kg) was close to the values for freshly dissected mucosae (51.6 mEq/kg) and for incubated mucosae (68.0 mEq/kg) that were previously reported by one group of investigators; smaller levels found in other studies may reflect an incomplete extraction of Cl^- from the tissue. Further studies showed that over one-half of the cell Cl^- was taken up into the mucosal cells in 2 min. This rate of Cl^- uptake was compared to acid production using the average wet weight per unit area in these experiments of 53 mg/cm^2; cell Cl^- uptake was calculated to be 4.9 μEq/cm^2/hr, a value slightly larger than the rate of acid secretion. The results suggest that much of Cl^- uptake occurs by exchange diffusion of Cl^- at the secretory surface.

8023 INTERACTIONS OF GASTRIC BLOOD FLOW, BARRIER BREAKER, AND HYDROGEN ION BACK DIFFUSION DURING ULCER FORMATION IN THE RAT.

(Eng.)

rsereau, W. A.; Hinchey, E. J. (Montreal General
sp., Montreal, Quebec H3G 1A4, Canada). *Surgery*
(3):248-251; 1978.

e interactions among gastric blood flow, H^+ back-
ffusion, and the effects of barrier breakers
re studied in a rat gastric chamber prepara-
on to clarify the respective roles of these
rameters in the pathogenesis of acute gastric
sions. Application of sodium taurocholate (STC)
the entire mucosal surface markedly increased
loss from the chamber in the normal flow study
ean, 133.1 ± 6.5 μEq/15 min), whereas reduction
the area of barrier break by 50% reduced the H^+
ss proportionally (mean 61.7 ± 7.2 μEq/15 min).
e application of STC to an area of 1 cm^2 (15%
rrier break) led to a H^+ loss of 23.2 ± 4.4 μEq/
min, which was not significantly different from
e control period. No mucosal lesions were found
ere mucosal blood flow was present. Interruption
blood flow markedly reduced the rate of H^+ back-
ffusion, as compared with normal flow groups
which either 100% or 50% of the area was
vered with STC, but there was no signifi-
nt difference with 15% barrier break whether
ood flow was interrupted or not. Complete
chemia resulted in ulceration, which was lim-
ed to the area pretreated with STC. The ap-
ication of STC to the squamous epithelium-lined
restomach failed to increase the permeability
this membrane to H^+ or Na$^+$ or to increase fluid
ux. Sodium entry into the chamber was noted
ter barrier break in the normal flow group; how-
er, the rate was not directly proportional to
e area of barrier break and was less as the area
barrier break decreased. Under conditions of
mplete ischemia, sodium influx was markedly re-
ced. It is concluded that, although H^+ back-
ffusion is a convenient measure of barrier per-
ability under conditions of normal mucosal blood
ow, during mucosal ischemia this parameter fails
reflect permeability because of decreased mu-
sal clearance of H^+. These findings would ex-
ain apparent controversy whereby ulceration oc-
rs under shock conditions in the absence of ap-
rent H^+ back-diffusion.

24 EVIDENCE FOR H_2-RECEPTOR-MEDIATED FEED-
BACK REGULATION OF HISTAMINE RELEASE FROM
DOCRINE CELLS IN THE RAT STOMACH. (Eng.) Hakan-
, R.; Larsson, L. I.; Liedberg, G.; Sundler, F.
ept. Pharmacology, Univ. Lund, Lund, Sweden). *J.
ysiol. (Lond.)* 276:151-157; 1978.

e effects of histamine H_2-receptor agonists and
the blockade of H_2-receptors on pentagastrin-
duced reduction of gastric histamine release was
udied in male Wistar or Sprague-Dawley rats. The
stric mucosal histamine level was measured after
c. injection of histamine dihydrochloride (0, 5,
, or 25 mg/kg) or infusion of histamine (50 mg/kg/
) or dimaprit (100 mg/kg/hr) with pentagastrin
jections of 1, 62.5, 125, 250, or 500 μg/kg.
ockade by the H_2-receptor antagonists, metiamide
0 mg/kg/hr or 10 mg/kg) and burimamide (20 mg/kg),
d by the H_1-receptor antagonist, mepyramine (30
mg/kg) was studied. In doses above 62.5 μg/kg, pentagastrin produced a 20-30% reduction of gastric histamine level 1 hr after injection ($p<0.001$ compared with untreated controls). Injected histamine inhibited this reduction if the histamine dose was high and the pentagastrin dose was low. Infused histamine or dimaprit prevented reduction of gastric histamine level at all dose levels of pentagastrin. When infusion of these receptor agonists was accompanied by infusion of the H_2-receptor antagonist, metiamide, the pentagastrin-induced release of histamine declined significantly ($p<0.001$) relative to saline-treated controls. The reduction of gastric mucosal histamine level after treatment with burimamide and pentagastrin was significant ($p<0.005$), as was the reduction caused by treatment with metiamide and pentagastrin ($p<0.001$) relative to rats treated with saline and pentagastrin. No significant lowering of gastric histamine content was noted when mepyramide and pentagastrin treatment was used. Similar results were obtained in intact and in antrectomized rats. To produce similar effects in vagotomized rats, higher doses of pentagastrin were required. The present study demonstrates a direct effect of the H_2-receptor antagonists on the histamine-storing endocrine-like cells in the oxyntic mucosa in the rat stomach. The effect is described as H_2-receptor mediated autofeedback, a mechanism whereby mobilized histamine inhibits further release of histamine from the cells.

8025 INHIBITION OF HISTAMINE-N-METHYLTRANSFERASE AND HISTAMINASE (DIAMINE OXIDASE) BY A NEW HISTAMINE H_2-RECEPTOR AGONIST, DIMAPRIT. (Eng.) Shaff, R. E.; Beaven, M. A. (Natl. Heart, Lung, Blood Inst., Natl. Inst. Health, Bethesda, MD 20014). *Biochem. Pharmacol.* 26(21):2075-2078; 1977.

The effects of Dimaprit on the *in vitro* activities of histamine decarboxylase (HD), diamine oxidase (DAO), and histamine-*N*-methyltransferase (HNMT) were investigated. HD was prepared from rat gastric mucosa, DAO from rat ileum, and HNMT from frozen guinea pig brain. Dimaprit was tested at 10^{-6}, 10^{-5}, 10^{-4}, 10^{-3}, and 2.5×10^{-3} M. Dimaprit had no effect on HD; it inhibited both DAO and HNMT noncompetitively, with apparent K_i values of $7\text{-}9 \times 10^{-6}$ M for HNMT and $2.5\text{-}3.0 \times 10^{-4}$ M for DAO. All values were the average of duplicate experiments. The results indicate that Dimaprit is a weak inhibitor of DAO and a stronger inhibitor of HNMT.

8026 IS HISTAMINE A MEDIATOR IN BILE-INDUCED GASTRIC MUCOSAL INJURY? (Eng.) Cheung, L. Y.; Porterfield, G. (Veterans Admin. Hosp., St. Louis, MO 63110). *J. Surg. Res.* 24(4):272-276; 1978.

The protective effect of histamine$_1$- and histamine$_2$-receptor antagonists on the mucosal permeability barrier and on gross mucosal injury was evaluated in anesthetized dogs. After i.m. injection of mepyramine (10 mg/kg) and continuous i.v. infusion of cimetidine (50 μg/kg/min), measurements of ion fluxes and the transmucosal potential difference (PD) were made, and the degree of mucosal injury was scored by an independent observer. No evidence of mucosal injury was seen in any of the dogs before the introduction of 5.0 mM Na taurocholate. Measurements continued after the taurocholate was added to the HCl bathing solution of the test mucosa. The degree of mucosal injury in antihistamine-treated dogs was not significantly different from that in untreated dogs (lesion index, 1.9 ± 0.3 versus 1.6 ± 0.5, resp.). The PD in control mucosa did not change over the course of the experiment. Antihistamine treatment did not change the PD; however, exposure of the test mucosa to taurocholate resulted in an immediate drop in PD ($p<0.01$). The net flux of H^+ was not altered by the administration of the H_1- and H_2-receptor antagonists. Following exposure of the test mucosa to taurocholate, there was a marked increase in H^+ loss ($p<0.05$) compared with control mucosa or test mucosa before the addition of taurocholate. The change in Na^+ efflux was similar to that of H^+. Exposure to taurocholate resulted in a significant ($p<0.05$) increase in sodium efflux into the lumen. Comparison of H^+ flux in antihistamine-treated dogs and in untreated controls showed that exposure to taurocholate in either group resulted in a significant increase in luminal loss of H^+ and that the rate of H^+ back-diffusion increased slightly in the treated dogs. The failure of antihistamines to prevent bile salt-induced disruption of the permeability barrier and to protect against gross mucosal injury does not support the concept that histamine is a mediator in bile salt injury.

8027 PROPERTIES OF K^+/H^+ EXCHANGE ATPase FROM DOG GASTRIC MUCOSA.

(Eng.) Scholes, P.; Lee, J. (Imperial Chemical Industries, Ltd., Mereside, Alderley Park, Macclesfield, Cheshire SK10 4TG, England). *Acta Physiol. Scand.* (Suppl.):427-434; 1978.

The suggestion that K^+ entry into vesicles prepared from dog gastric mucosa is important in maintaining optimum activity of the electrically neutral ATP hydrolysis-driven transport of H^+ into these vesicles was tested, and the hypothesis that K^+ ions act as counterions for H^+ transport was investigated. H^+ transport into microsomal vesicles from dog gastric mucosa was completely abolished by nigericin (2.5 μg/ml), which catalyzes a tightly coupled exchange of K^+ and H^+. Since this abolition could not be achieved by valinomycin (1.25 mg/ml) or FCCP (4.5×10^{-6} M) alone but only in combination, it appears that nigericin catalyzes an exchange of one H^+ ion for one K^+ ion. Optimum proton transport driven by ATP proceeded only when K^+ ions were present within the vesicles. Thus, proton transport was greatly diminished in media in which the K^+ ions were replaced by Na^+ ions or choline ions. However, when K^+-loaded vesicles were prepared, proton transport proceeded rapidly,
irrespective of the type of cation in the externa
medium. ATP hydrolysis-driven transport of H^+ i
was only moderately reduced when Cl^- ions were r
placed by glucuronate or SO_4^{2-} ions, suggesting
that Cl^- ions are not important in the exchange
H^+ and K^+ ions *per se*. However, the slow phase
observed in the time-course of ΔpH in the absenc
of Cl^- was similar to that observed in low K^+ me
This finding suggests that the equilibration of
during the 15 min preincubation prior to the add
tion of MgATP is decreased in the absence of Cl^-
ions. The cotransport of K^+ and Cl^- ions across
the luminal membrane of the parietal cell in par
lel with the H^+/K^+ exchange ATPase might be an i
portant mechanism for HCl secretion.

8028 EFFECT OF METABOLIC ACIDOSIS ON GASTRI
ACID SECRETION AND SERUM GASTRIN.

(En
Vogel, S. B.; Ishiguro, N.; Manabe, M.; Eisenber
M. M. (Univ. Minnesota Medical Sch., Minneapolis
MN). *Surg. Forum* 28:370-372; 1977.

The role of metabolic acidosis in acid secretion
and the effect of metabolic acidosis on direct
vagal parietal cell response and vagal antral
gastrin mechanisms of acid production was invest
gated. Gastric acid secretory and serum gastrin
level responses were determined in six mongrel
dogs with standard gastric fistulas during mild
(pH 7.2-7.3; 2% NH_4Cl infusion, 3-4 hr) and
severe (pH 7.1-7.2; 4% NH_4Cl infusion, 3-4 hr)
metabolic acidosis alone, following maximal
parietal cell (160 mg/kg/hr histamine) and
vagal (150 mg/kg, i.v., 2-deoxy-D-glucose [2DG])
stimulation, and following superimposition of pa
etal cell or vagal stimulation on mild or severe
acidosis. All experiments were repeated after t
dogs underwent truncal vagotomy. Peak acid outp
(PAO) in mild and severe acidosis was 7.4 ± 2.9
and 5.1 ± 2.3 mEq H^+/30 min, resp., and occurred
after 5-6 hr of NH_4Cl infusion. Truncal vagotom
produced a marked reduction of PAO in mild acido
but only a 50% reduction in severe acidosis (0.5
versus 2.2 ± 1.1 mEq H^+/30 min, resp.). Both m
and severe acidosis markedly reduced histamine-
stimulated gastric acid secretion (from 26.2 ±
to 19.7 ± 1.4 or 13.7 ± 1.5 mEq H^+/30 min, resp.
The 40% reduction in gastric acid secretion fol
ing truncal vagotomy was only slightly augmente
mild acidosis and was unaffected by severe acid
Only mild acidosis affected 2DG-stimulated acid
secretion; PAO after 2DG was 10.2 ± 3.4 mEq H^+/
min and rose to 18.6 ± 4.4 mEq H^+/30 min during
mild acidosis plus 2DG. Truncal vagotomy aboli
the effect of 2DG alone; but small yet importan
acid secretory responses persisted during mild
severe acidosis (1.4 ± 0.4 and 2.8 ± 1.2 mEq H^+
min, resp.). The serum gastrin level increased
a control value of 29 ± 3 pg/ml to 82 ± 17 pg/m
mild acidosis and to (34 ± 14)-(92 ± 17) pg/ml
(range) in severe acidosis; truncal vagotomy ab
ished these effects. 2DG stimulation increased
serum gastrin level (from 22 ± 6 to 49 ± 12 pg/
further increases occurred during mild (from 21
4 to 60 ± 13 pg/ml) and severe acidosis (from 2
4 to 96 ± 7 pg/ml) and were abolished by trunca

vagotomy. It is concluded that the effects of metabolic acidosis on gastric acid and serum gastrin responses depend largely on intact vagal pathways, that metabolic acidosis has a direct effect on parietal cells, and that NH$_4$Cl or acidosis either decreases the sensitivity of the parietal cell or interferes in the histamine-parietal cell axis.

8029 THE EFFECTS OF ASPIRIN AND OTHER NON-STEROID ANTI-INFLAMMATORY/ANALGESIC DRUGS ON GASTRO-INTESTINAL MUCUS GLYCOPROTEIN BIOSYNTHESIS IN VIVO: RELATIONSHIP TO ULCEROGENIC ACTIONS. (Eng.) Rainsford, K. D. (Univ. Tasmania Medical Sch., G.P.O. Box 252C, Hobart, Tasmania, 7001, Australia). *Biochem. Pharmacol.* 27(6):877-885; 1978.

The effects of aspirin and related nonsteroid anti-inflammatory (NSAI) drugs on the incorporation of radio-labeled precursors into mucus glycoproteins isolated from the rat gastrointestinal tract were studied. The p.o. administration of aspirin at 200 mg/kg caused a marked inhibition of the incorporation of $^{35}SO_4{}^{-2}$ into isolated gastric glycoproteins at 5 hr or later following drug administration. In contrast, glycoprotein synthesis inhibition was only evident 24 hr after the administration of the same dose of salicylic acid. Aspirin failed to inhibit the incorporation of L-[U-^{14}C]threonine or [1-^{14}C]acetate into proteins or glycoproteins, resp., when these labeled precursors were given i.p. 5 min after the drug. To consider the possibility that the diverse systemic effects of salicylates may alter the pattern of organ uptake or metabolism of labeled acetate, radioactive acetate was given p.o. 5 min after the aspirin dose. Aspirin inhibited the incorporation of radioactive acetate, but the total uptake of [1-^{14}C]acetate by the gastric mucosa tissue was also reduced under these conditions, suggesting that the apparent inhibitory effect could be due to variable effects of the drug on uptake of the radioactive acetate. Of the NSAI tested (i.e., diclofenac, flurbiprofen, indomethacin, suprofen, azopropazone, dextropropoxyphene napsylate, diflunisal, fenclofenac, flufenamic acid, naproxen, paracetamol, and sulindac), only indomethacin, diclofenac, flurbiprofen, and suprofen caused inhibition of $^{35}SO_4{}^{-2}$ incorporation into gastric mucosal glycoproteins. When correlated with the gastric ulcer indices of these compounds, it was evident that the more potent ulcerogenic drugs caused a statistically significant reduction in radiosulfate incorporation, whereas those with little or no ulcerogenic activity did not. All salicylates tested caused an inhibition of $^{35}SO_4{}^{-2}$ uptake into glycopeptides isolated from the gastric mucosa incubated *in vitro*, with salicylate being a more potent inhibitor than aspirin. Maximal gastric mucosal tissue concentrations of salicylates were achieved at 10-15 min after p.o. administration, which coincided with a peak of salicylates in the blood. Much lower concentrations of salicylates were present in the intestinal contents and mucosa compared with those in the stomach. There was a rapid and appreciable rate of hydrolysis of aspirin to salicylate in the gastric mucosa.

Pancreas

54 PANCREATIC SECRETION OBTAINED BY ENDOSCOPIC CANNULATION OF THE MAIN PANCREATIC
CT AND SECRETIN RELEASE AFTER DUODENAL ACIDIFICA-
ON IN MAN. (Eng.) Hanssen, L. E.; Osnes, M.;
ren, J. (Ulleval Hosp., Oslo, Norway). *Scand. J.*
stroenterol. 13(3):325-330; 1978.

e effect of acid in the duodenum on pancreatic
cretion of water, bicarbonate, and α-amylase and
the release of secretin was studied in 12 pa-
ents suffering from gastrointestinal disease but
ving normal endoscopic retrograde pancreato-
aphies. The main pancreatic duct was cannulated
th a teflon catheter by means of a side-viewing
odenoscope. Six of the patients received a du-
enal infusion of 40 ml of 100 mM HCl over 5 min;
e others served as controls for basal pancreatic
cretion. Pancreatic juice was collected for 20-
min in 5-min samples, and blood was drawn
intervals for immunoreactive secretin (IRS)
termination by radioimmunoassay. In the control
~~oup, no significant change~~ was observed in the
S level (range, 1.4 ± 0.3 to 1.9 ± 0.4 pM), bi-
rbonate concentration (range, 72 ± 5 to 73 ± 7
), bicarbonate output (range, 0.04 ± 0.02 to
06 ± 0.03 mmol/5 min), α-amylase concentration
ange, 464 ± 38 to 508 ± 36 kU/5 min), or the α-
ylase output (range, 0.3 ± 0.1 to 0.4 ± 0.2
/5 min). Duodenal acidification produced an
crease in the immunoreactive secretin level (IRS,
ak at 7 min of 15.8 ± 2.2 pM) and in the pancreatic
cretion of water and bicarbonate. In the third 5-
n sample, the maxima for pancreatic flow rate (11.5
.7 ml/5 min, $p<0.02$), bicarbonate concentration (122
6 mM, $p<0.02$), and bicarbonate output (1.4 ± 0.4
ol/5 min, $p<0.02$) were reached. After acidification,
e output of α-amylase was significantly ($p<0.02$)
gher and the concentration of α-amylase decreased,
aching its lowest point in the third 5-min sample
37 ± 22 kU/l, $p<0.02$). Using the improved
chnique of endoscopic cannulation of the main
ncreatic duct, the basal levels of pancreatic
cretion and those stimulated by HCl were deter-
ned. The observed rise in plasma IRS levels is
ought to be responsible for the increased pan-
eatic flow rate and bicarbonate output.

55 THE EFFECT OF PREDOMINANTLY α-ADRENERGIC DRUGS, INDIRECT SYMPATHOMIMETICS AND DOPA-
NE ON EXOCRINE PANCREATIC FUNCTION: STUDIES IN
E ISOLATED CAT PANCREAS. (Ger.) Heidbreder, E.;
eber, P.; Heidland, A. (Medizinische Universi-
tsklinik, Josef-Schneider-Strasse 2, D-8700 Wurz-
rg, W. Germany). *Res. Exp. Med. (Berl.)* 172(1):
-108; 1978.

e influence of predominantly α-adrenergic sub-
ances (norepinephrine, epinephrine [each 0.005-
6 μmol, perfusion], phenylephrine [0.3-0.6 μmol,
rfusion]), indirect sympathomimetics (ephedrine,
ramine [each 0.3-0.6 μmol, perfusion]), and dopa-
ne (0.3-0.6 μmol; perfusion) on the exocrine
nction of the isolated pancreas of adult cats
s studied. The injection of epinephrine and norepinephrine induced a rapid depression of flow rate and a simultaneous increase of the perfusion pressure. Phenylephrine, ephedrine, tyramine, and dopamine did not change the perfusion pressure or the hydrokinetic function (flow rate, calcium, and chloride secretion). The secretion of protein and enzymes was enhanced both in intact animals and in cats pretreated with reserpine (1-1.5 mg/kg, i.p.) or 6-hydroxydopamine (60 mg/kg, i.v.). The pancreatic protein secretion was inhibited by both α-adrenolytic and β-adrenolytic substances, as well as by tetracain (5×10^{-4} M, perfusion) and atropine (2.5×10^{-9}-2.5×10^{-7} M, perfusion). It is concluded that predominantly α-adrenergic substances stimulate pancreatic enzyme secretion.

8056 THE ACTION OF DOPAMINE ON BASAL PANCREATIC SECRETION IN MAN. (Ger.) Lankisch, P. G.; Koop, H. (Medizinische Universitatsklinik, Robert-Koch-Str. 40, 3400 Gottingen, W. Germany). *Dtsch. Med. Wochenschr.* 103(9):391-392; 1978.

The effect of dopamine (4 μg/kg/min, 45-min infusion) on basal pancreatic secretion was studied in five male volunteers. Dopamine failed to influence basal bicarbonate and enzyme (trypsin and amylase) secretion. This finding is contrary to observations in dogs, and indicates that dopamine may be infused for circulatory shock in acute pancreatitis without reservations.

8057 DIFFERENTIAL RATES OF DIGESTIVE ENZYME TRANSPORT IN THE PRESENCE OF CHOLECYSTOKININ-PANCREOZYMIN. (Eng.) Rothman, S. S.; Wilking, H. (Dept. Physiology, Univ. California, San Francisco, CA 94143). *J. Biol. Chem.* 253(10):3543-3549; 1978.

Previous studies in which a peptide mixture containing cholecystokinin-pancreozymin (CCK-PZ) had stimulated digestive enzyme secretion by the pancreas in a nonparallel manner were repeated using the original preparation, the pure CCK-PZ peptide, and a synthetic, biologically active, COOH-terminal octapeptide fragment of the whole molecule. When CCK-PZ was added to the medium bathing rabbit pancreas *in vitro*, digestive enzyme secretion was enhanced in a dramatic nonparallel fashion. Protein, trypsinogen, and chymotrypsinogen secretion all increased, but increases in the secretion of the two enzymes were strikingly dissimilar. For the peak period, trypsinogen secretion was increased 15 times the control rates, while chymotrypsinogen secretion was increased only about 4 times. This difference was maintained over the 3-hr course of the experiment and was seen over a considerable range of protein concentrations. The effect was stimulus-bound and could not be ascribed to any error in measurement. The response was essentially the same whether the pure CCK-PZ polypeptide or an impure mixture of peptides containing 25% CCK-PZ by weight was tested. Unlike CCK-PZ, acetyl-β-methylcholine (MCh) increased trypsinogen and chymotrypsinogen secretion in a roughly parallel or quantitatively equivalent fashion. Chymotrypsinogen output averaged 25 times the control rates at the peak, with increases as large as 125-fold, over 6 times the average peak response to CCK-PZ. Similarly, the COOH-terminal octapeptide fragment of CCK-PZ produced parallel stimulation of the digestive enzymes; the chymotrypsinogen output average 14 times the control rate for the peak period and increases as great as 100-fold were observed. Samples of CCK-PZ-stimulated secretion did not inhibit either chymotrypsinogen activation or chymotrypsin activity, and thus, the apparent paucity of chymotrypsinogen in CCK-PZ-stimulated secretion cannot be attributed to the secretion of an inhibitor of activity or activation in response to CCK-PZ. Since the digestive enzymes are apparently stored as mixed arrays within individual secretory granules, the differential secretion observed cannot be explained by the exocytosis of their contents.

8058 ACTION OF FATTY ACIDS ON THE EXOCRINE PANCREATIC SECRETION OF THE CONSCIOUS RAT: FURTHER EVIDENCE FOR A PROTEIN PANCREATIC INHIBITORY FACTOR.

(Eng.) Demol, P.; Sarles, H. (Institut National de la Sante et de la recherche medicale, 46 Chemin de la Gaye, Marseille 13009, France). *J. Physiol. (Lond.)* 275:27-37; 1978.

The inhibitory effect of the intraduodenal infusion of oleic acid on pancreatic protein secretion, observed in conscious bile duct-ligated rats, was investigated by determining which nutrients (i.e., pure oleic acid, sodium oleate dispersed in polysorbate 80, esterified oleic acid in the form of olive oil, caprylic acid, butyric acid, glucose, and NaCl) could induce this inhibition after the normal bile flow was reintroduced into the duodenum. In the first series of experiments, bile but not pancreatic juice was reintroduced. Pancreatic flow rate increased significantly during 60 min after starting an infusion of oleic acid, with a peak at 30 min (+37% of plateau); protein concentration increased slightly (+3.9%) at 30 min and then decreased rapidly and remained significantly decreased in comparison with basal values (-65% in the last experimental period). Sodium oleate dispersed in polysorbate 80 produced an increase in volume and decrease in protein similar to those seen with pure oleic acid. The volume increase with sodium caprylate was less than that with oleic acid; the initial increase in protein concentration and output was greater than with oleic acid but the delayed inhibition was less marked. Volume, protein concentration, and protein output increased slightly but not significantly during sodium butyrate infusion, and there was no delayed inhibition. When olive oil was infused, volume increased slowly and progressively and was significantly increased only during the last two periods. When both bile and pancreatic juice were reintroduced into the duodenum, the basal protein secretion was lower than in the first series. However, the decrease in protein concentration and output following the administration of oleic acid showed the same pattern as when pancreatic juice flow alone was diverted. The increase in volume produced by olive oil was delayed compared with the response to oleic acid but reached a slightly higher peak; pancreatic protein output was comparable to that seen after oleic acid infusion, and the delayed inhibition even more marked (-70%). No modification in vol or protein secretion was seen during or after 5% glucose or 0.9% NaCl infusion. A 30% glucose infusion produced a delayed increase in volume, wh was maximal 60 min after the end of infusion. P tein concentration remained stable. A 5.4% sali infusion induced a 32% decrease in protein conce tration but did not modify the volume. Delayed cretion produced by intraduodenal oleic acid infusion is not dependent on bile or pancreatic ju The action of oleic acid is not a pathological phenomenon. Fatty acids must be free or saponif but not esterified in the form of triglycerides produce the response.

8059 PANCREATIC RESPONSE AND PLASMA SECRET CONCENTRATION DURING INFUSION OF LOW DOSE SECRETIN IN MAN.

(Eng.) Schaffalitzky de Muckadell, O. B.; Fahrenkrug, J.; Watt-Boolsen, S.; Worning, H. (Bispebjerg Hosp., Bispebjerg Bakke 23, DK-2400 Copenhagen NV, Denmark). *Scan J. Gastroenterol.* 13(3):305-311; 1978.

To elucidate the physiological role of secretin in the regulation of pancreatic secretion, the secretin concentration in peripheral venous bloo and the bicarbonate secretion into the duodenum was measured in 10 normal human subjects during i.v. infusions of low doses of secretin. The du denum was intubated and fasting secretion of bicarbonate was measured during gastric aspiration Afterwards, pancreatic secretion was stimulated secretin at dose levels of 0.01, 0.03, 0.1, and 0.3 clinical U (CU)/kg/hr. The concentration of secretin in infusates (actual stimulation attain 85%) and in venous plasma was measured by radioi munoassay. The obtained increase in plasma secretin concentration (actual concentration minus fasting concentration) showed a linear correlati (r=0.915) with the measured secretin infusion rate. The median metabolic clearance rate was 15.7 ml/kg/min and the median half-life of exoge secretin was 3.8 min. Physiological plasma concentrations of human secretin (below 10 pM) were obtained at doses of secretin lower than 0.1 CU/ hr. The corresponding levels of bicarbonate secretion ranged from 0 to 22.93 mmol/hr. The sti ulated increase in bicarbonate concentration was linearly correlated (r=0.828) with the logarithm of the increase in venous concentration of secretin. The secretion of bicarbonate into the du denum was markedly higher than in the fasting st even at the lowest rate of stimulation (the medi concentrations were 0.41 pmol/hr during fasting, 1.35 pmol/hr at the 0.01-CU secretin dose, and 2 pmol/hr at the 0.30-CU secretin dose). The expe iments show that even low doses of secretin can stimulate bicarbonate secretion in the duodenum. The secretin assay can detect a significant increase in secretin concentrations during infusio of a dose as low as 0.01 CU/kg/hr.

8060 INHIBITION OF SECRETIN-STIMULATED EXOCRINE PANCREATIC SECRETION BY DIAZOXID IN THE RAT.

(Eng.) Pedrazzoli, S.; Dodi, G.;

Militello, C.; Favretti, F.; Brandstetter, S.; Lise, M. (Clinica Chirurgica Universita degli Studi, I-35100 Padova, Italy). *Eur. Surg. Res.* 10(1):33-39; 1978.

The effects of diazoxide, a known insulin inhibitor, on the basal, secretin-, and cholecystokinin-pancreozymin (CCK-PZ)-stimulated pancreatic exocrine secretion were studied in unanesthetized male Italicus rats. The rats were stimulated with an intra-aortic injection of secretin (18 U/kg), CCK-PZ (25 U/kg), or saline (1 ml, control). Doses of diazoxide (22.5 or 45 mg/kg) or saline (1 ml) were injected intra-arterially, 5 min before and 5 min after the stimulation. The volume of pancreatic juice and the protein and bicarbonate concentrations and outputs were determined at 10-min intervals. The basal pancreatic secretion was not modified by any of the doses of diazoxide used. Secretin significantly ($p<0.001$) increased the volume of pancreatic juice (from 5.16 ± 0.92 to 9.16 ± 1.72 μl/min) and the bicarbonate concentration (from 30.35 ± 3.9 to 47.49 ± 5.1 mEq/l) and output (from 156.60 ± 3.58 to 416.04 ± 6.70 mEq/min); these increases were inhibited by the higher dose of diazoxide while the lower dose reduced the volume response only. No significant variation in the pancreatic flow and bicarbonate concentration and output was seen in controls injected with diazoxide and saline or with saline only. Protein concentration and output were not significantly modified in rats treated with secretin or diazoxide or both. CCK-PZ significantly increased the protein concentration (from 2.47 ± 0.6 to 7.50 ± 0.95 g%, $p<0.001$) and protein output (from 77.73 ± 33.79 to 245.70 ± 38.90 μg/min, $p<0.01$). Diazoxide did not significantly influence these responses. Diazoxide did not modify the CCK-PZ-stimulated pancreatic secretion. The authors propose that the inhibition of insulin secretion by diazoxide may influence the interaction between secretin and the secretin receptors of the centroacinar and ductal cells. Direct action of diazoxide on these cells was ruled out because diazoxide did not modify the basal secretion. Since diazoxide inhibits the pancreatic exocrine response to secretin but does not modify the CCK-PZ stimulated secretion, it is suggested that insulin may have a permissive role on the secretin-stimulated pancreatic secretion.

8065 DETERMINATION OF THE BILIARY TREE CAPACITY OF THE RAT IN ITS DISTENDED AND NONDISTENDED STATE USING ^{35}S-SULFOBROMOPHTHALEIN GLUTATHIONE (^{35}S-BSP-GSH) AS A MARKER. (Eng.) Dammann, H. G. (I. Medical Clinic, Univ. Hamburg, 2 Hamburg 20, W. Germany). *J. Physiol. (Paris)* 73(1):37-46; 1977.

BSP-glutathione was used as a marker to measure the biliary tree volume of male Wistar rats. Two methods were used to calculate the volume in the distended and nondistended state; one method is a modification of a previously described method in which biliary dead space is calculated as the volume of bile collected between the i.v. injection of ^{35}S-BSP-glutathione and its appearance in collected bile, while the other is a new method based on the assumption that the first measurable radioactivity following marker injection indicates the time of appearance of the injected marker in the right and left hepatic duct. The biliary tree capacity in the nondistended state was only 77.8% of that reported in previous studies when determined by the first method and 72% of previous values when determined by the second method. The values were 30.4 ± 5.2 and 20.0 ± 3.7 μl by the first and second methods, resp., corresponding to 2.49 ± 0.37 and 1.67 ± 0.42 μl/g liver; the differences between the values obtained by the two methods were statistically significant in both cases ($p<0.05$). The distended biliary tree volume was determined two different ways. In one set of experiments, ^{35}S-BSP-glutathione was injected i.v. 2-3 sec before terminating a 15-min biliary obstruction; in the other experiments, the injection was administered 60 sec before terminating the struction. The new method for calculating biliary volume was used in both cases. The distended volume calculated after injecting the marker 2-3 sec before terminating biliary obstruction was 69.8 ± 7.1 μl or 5.07 μl/g liver, whereas the values obtained after injecting the marker 60 sec before terminating the obstruction were 59.6 ± 6.7 μl and 4.24 ± 0.94 μl/g liver. These levels were all significantly lower ($p<0.05$) than those calculated using the previously published method (119.8 ± 12.7 μl and 8.84 μl/g liver). The capacity was also significantly lower when the marker was injected at 60 sec than at 2-3 sec. It is concluded that determining biliary tree volume by administering the marker 60 sec before terminating an obstruction gives a more accurate estimate of the true biliary tree capacity in the distended state.

8066 EXPERIMENTAL STUDIES ON CONTINUOUS HYPOTHERMIC LIVER PERFUSION WITH A SYNTHETIC SOLUTION CONTAINING GELATIN POLYPEPTIDES (HAEMACCEL).

(Eng.) Fuller, B. J.; Attenburrow, V. D.; Newsome, C. (Royal Free Hosp. Sch. Medicine, London, England). *Cryobiology* 15(3):279-289; 1978.

A rat liver model was used to study preservation by continuous hypothermic perfusion, and experiments were designed to investigate whether changing the perfusion pressure would alleviate the problems of increased resistance to flow encountered during hypothermic liver perfusion. Perfusion for 5 or 24 hr with a defined solution containing Haemaccel as colloid at a temperature of 5-7 C was found to result in good preservation of the metabolic activity of the livers, as assessed by the ability of the tissue to synthesize urea (8.89 ± 1.34 μmol/g at 5 hr, 7.18 ± 1.23 μmol/g at 24 hr; both perfusions at 20 cm H_2O) and to take up galactose (40.78 ± 4.83 μmol/g at 5 hr, 34.76 ± 5.36 μmol/g at 24 hr). In common with other continuous perfusion methods, there was increasing evidence of cell damage as perfusion progressed; at 5 hr, biopsy specimens showed clearly visible sinusoidal channels and a well preserved chain-like formation of the hepatocytes, whereas at 24 hr, there were regions in which the sinusoidal spaces were small or indistinguishable, even though the adjacent branches of portal vein, artery, and central vein were patent. In addition, there was a depletion of cellular K^+ ($p<0.05$) and an increase in tissue water content ($p<0.01$) in 24-hr perfused livers compared with 5-hr perfused livers. There was a considerable increase in vascular resistance, as indicated by a fall in flow rate at a constant pressure, in the later stages of perfusion; flow rate after 24 hr was reduced to approximately 30% of that after 5 hr. Further studies are necessary to analyze, in a controlled fashion, the nature of the damage incurred by the liver during storage and the requirements for maintenance of a viable graft by hypothermia.

8067 CORRECTION OF HEPATOCELLULAR DYSFUNCTION DURING ENDOTOXEMIA.

(Eng.) Heimberger, S. L.; McDougal, W. S.; Wilmore, D. W.; Pruitt, B. A., Jr. (United States Air Force Medical Center, Ke sler Air Force Base, MS 39534). *J. Surg. Res.* 24 (5):442-448; 1978.

Because endotoxin exerts a variety of effects on physiologic function, a nonlethal endotoxemia model was established in dogs to examine its effect on th alterations in transport function of the hepatocyte Indocyanine green (ICG) was used as a clearance marker of hepatic membrane transport, and the impact of energy substrate on hepatic transport was determined. No change in hepatic blood flow, plasma volume, or blood pH or gas concentrations was observed following the i.v. injection of *Escherichia coli* endotoxin, given as 0.1 mg/kg body weight of lipopolysaccharide followed by a 0.05-mg/kg/hr infusion for 2 hr. However, marked alterations in the kinetics of ICG occurred following administration; the initial rapid extraction reflecte by the K_1 rate constant decreased ($p<0.001$) and back diffusion, thought to suggest increased membrane permeability (reflected in part by the K_2 constant), increased ($p<0.01$). These alterations in dye clearance suggest a direct effect of endotoxin on hepatocyte transport, substantiating the earlier observations of similar changes that occur in bacteremic, thermally injured patients. The alterations in hepatic energetics were returned to normal by the simultaneous administration of a 50% glucose solution (2 g/kg) and insulin (0.2 U/kg), followed by an infusion of 0.5 g glucose/kg/hr and 0.2 U insulin/kg/hr. In this model system, endotoxin is thought to have a direct effect on the hepatocyte, markedly altering cellular energetics and hepatocyte transport, and its action may accour for the progressive changes in hepatic function tha are frequently observed in critically ill infected patients.

8068 THE USE OF FINE-NEEDLE ASPIRATION BIOPSY FOR THE DIAGNOSIS OF HEPATIC STEATOSIS IN RATS.

(Eng.) Boelsterli, U.; Zbinden, G. (Inst Toxicology, Univ. Zurich, Schorenstrasse 16, 8603 Schwerzenbach, Switzerland). *Toxicol. Lett.* 2(1): 35-43; 1978.

The value of fine needle aspiration biopsy (FNAB) for the examination of experimental liver lesions in small laboratory animals was investigated in male ZUR:SIV-Z strain rats with experimental fatty liver. Rats were fed a high fat diet (39.7% butter, 5% cholesterol) with or without simultaneous treatment with chlortetracycline (80 mg/kg, intragastrically, 5 times/week), and FNAB was performed on days 2, 4, 8, and 16 of treatment. The specimens were stained with the Masson-Goldner and Van Gieson methods (MGG) or with hematoxylin and Fettr 7B. The appearance of these biopsy specimens was compared with that of specimens obtained at necrop and stained by the same methods. After MGG staining, the cytoplasm of the cells taken by FNAB from the untreated control rats had a fine granular appearance. Stainable fat was not increased in the

hlortetracycline-treated rats receiving a normal
iet. In animals fed the high fat diet, with and
ithout chlortetracycline, diffuse vacuolization
as seen in the MGG-stained smears, and a distinct
ccumulation of fat droplets was seen in cells
tained with Fettrot 7B and hematoxylin. This
ccumulation was seen even after 2 days, and the
umber of fat droplets increased over the study
eriod. The degree of fatty change was scored
sing arbitrary units in both the specimens taken
y biopsy and those taken at necropsy. Scoring
as identical in both the biopsy and necropsy speci-
ens in 60% of the cases. In 38%, scoring differed
y 1 unit, and the higher score was usually ob-
ained in the necropsy slide. The scores in the
wo specimens differed by 2 units in only two cases.
he safety of FNAB was confirmed by repeated punc-
ure of the same liver lobe (40 punctures in 10
eeks). This treatment resulted in small necroses
nd hemorrhages that were rapidly organized without
ignificant distortion of the liver structure. It
ppears that FNAB is useful in detecting early
orphologic liver changes and in monitoring their
rogression, without the necessity of sacrificing
arge numbers of animals.

069 A COMPARISON OF METHODS FOR BILE SALT POOL SIZE MEASUREMENTS IN THE PRAIRIE DOG ALLSTONE MODEL.

(Eng.) Meyer, P. D.; DenBesten, L.
Veterans Admin. Hosp., Iowa City, IA 52242). *Proc.
oc. Exp. Biol. Med.* 156(3):452-456; 1977.

modified isotope-dilution technique for measuring
ile salt pool size was compared with the wash-out
echnique in the prairie dog gallstone model.
nolelithiasis was induced by feeding high-choles-
erol chow. Fasting animals received ^{14}C-labeled
nolic acid i.v. and a gavage feeding of a lipid-
rotein emulsion to stimulate gallbladder contrac-
ion. Twelve hours later, the cystic duct was
igated, and the common duct was cannulated. Gall-
ladder bile salt and bile salt from the first per-
od hepatic collection were determined by mass, and
adioactivity was also determined. The radioactivity
dministered was corrected for losses by mul-
iplying by e^{-kt}, where k is the fractional pool
oss per unit time (t). The previously reported
sotope-dilution technique (which mathematically
ssumes no losses, so that k=0 and e^{-kt}=1) was
sed to estimate pool size in computing k; the
aily synthesis rate was assumed to be 24 times the
ourly synthesis rate as determined after wash-out.
ne radioactivity from gallbladder bile and the
irst collection of hepatic bile was subtracted
rom this corrected radioactivity. This computa-
ion yields the radioactivity actually contained
n the animal after the first hepatic bile collec-
ion. This radioactivity is divided by the spe-
ific activity of bile salt from the second-period
epatic bile collection; this constitutes the "pool
emaining" in the animal after the first-period
epatic bile collection. The sum of the bile salt
n the gallbladder, first-period hepatic bile,
nd pool remaining constitutes the total bile salt
ool. The bile acid pool as calculated by the
odified isotope-dilution technique was 333 ± 104
µmol in controls and was 276 ± 84 µmol as calculated by washout. The average basal synthesis rate was 2.51 ± 1.16 µmol/hr, determined as the "plateau" of the wash-out curve. The difference between the two methods varied in magnitude but was consistent and statistically significant ($p<0.001$). The pool size as measured by isotope dilution was 431 ± 137 µmol, and by wash-out was 357 ± 120 µmol ($p<0.001$). Basal synthesis rate was 2.45 ± 1.06 µmol/hr. Wash-out pools corrected for recovery of radioactivity agreed very well with pools calculated by isotope dilution. These studies indicate that the modified isotope-dilution technique yields values for bile salt pool sizes consistently higher than those of the wash-out technique. The observed differences in pool size measurement apparently reflect an underestimation by the wash-out technique, possibly due to some portion of the pool, previously equilibrated with exogenous isotope, being unavailable for "wash-out" and measurement.

8070 REGULATION OF THE VOLUME OF ISOLATED RAT HEPATOCYTES IN HYPOOSMOTIC MEDIUM.

(Fre.) Poggioli, J.; Mazet, J. L.; Claret, M. (Laboratoire de Physiologie comparee et de Physiologie cellulaire, C.N.R.S. Universite Paris-XI, 91405 Orsay, Paris, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 285: 1467-1470; 1977.

Changes in the volume of isolated rat hepatocytes were studied 2 min to 2 hr after incubation in minimum essential medium (MEM, 37 C, pH 7.4) with NaCl concentrations ranging from 0 to 256 mM. The effect of ouabain addition (10^{-3} M) to the MEM was also observed. MEM with 185 mM NaCl increased cell volume to 150% immediately after incubation; the cell volume decreased to 106% of the initial volume after 1 hr of incubation. MEM with 92 mM NaCl increased cell volume to 260% of the inital volume after 2 min of incubation; it decreased to 150% of the initial volume 2 hr after incubation. Ouabain had no effect on the initial increase in cell volume induced by NaCl; ouabain only slightly affected the long-term change in cell volume with MEM containing 185 mM NaCl and had no effect on the cell volume with MEM containing 92 mM NaCl. Potassium and amino acid losses from the cells were 82 nmol/mg and 60 nmol/mg, resp., after 150 min. Thus, potassium or amino acid loss from the hepatocytes incubated in MEM with NaCl had no effect on the regulation of hepatocyte volume. The authors suggest that other mechanisms, such as a sodium pump (as in the kidneys), a contractile membrane system, or a decrease in the activity of osmotic particles by their binding to intracellular sites, may be involved in the regulation of hepatocyte volume.

8071 DEMONSTRATION OF AUTOANTIBODIES IN LIVER DISEASE USING INDIRECT IMMUNOFLUORESCENCE.

(Ger.) Storch, W. (Neurologische Klinik, Karl-Marx Universitat, Karl-Marx-Stadter-Strasse 50, DDR-7039

Leipzig, E. Germany). *Dtsch. Gesundheitsw.* 33(6): 257-265; 1978.

A synopsis of antibodies that appear in liver disease is presented. Antibodies are considered to be of diagnostic value and may provide information about pathogenesis, etiology, therapy, course of the disease, and prognosis. The antibodies, demonstrable by indirect immunofluorescence, include those against nuclear material (antinuclear factors), mitochondria, smooth muscle, microsomes, connective tissue, endothelium, bile ducts, bile duct epithelium, bile canaliculi, hepatic cytoplasm, immunoglobulins, thyreoglobulins, microsomal thyroid antigen, parietal cells, brush borders of proximal tubules in rat kidneys, lymphocytes and thrombocytes, collecting tubules, loop of Henle cells, and various proximal and distal renal tubule cells. Demonstration of humoral autoantibodies indicates that the tolerance to those particular antigens has been decreased. In liver disease, especially in chronic aggressive hepatitis, there are various groupings of disease, which may or may not be associated with antibodies. In differential diagnosis, specific antibodies demonstrated may be informative in cases of acute viral hepatitis, icterus of unknown etiology, chronic active hepatitis, lupoid hepatitis, and hepatitis of viral origin. Antibodies detected may provide clues about the identity of some forms of hepatitis responding to immunosuppressive therapy, about some forms possibly correlated with alpha-1-antitrypsin deficiency, and about the presence of active lupus erythematosus disseminatus.

8072 PREFERENTIAL LOCALIZATION OF RADIOLABELED LIPOSOMES IN LIVER.

(Eng.) Hinkle, G. H.; Born, G. S.; Kessler, W. V.; Shaw, S. M. (Tulsa Medical Coll., Tulsa, OK 74114). *J. Pharm. Sci.* 67(6):795-798; 1978.

Liposome formulations were studied to achieve an efficient entrapment procedure for the production of liposomes of ^{99m}Tc-pentetic acid (^{99m}Tc-I). The entrapment efficiency was studied by separation of the product using column chromatography. The mean percentage of ^{99m}Tc-I activity in the liposome fractions of negatively charged liposomes, as calculated from a total of six entrapment studies, was 1.86 ± 0.34%. The mean percentage of ^{99m}Tc-I activity in the liposome fractions of positively charged liposomes, as calculated from 12 entrapment studies, was 8.14 ± 1.66%. A 60-min sonication time produced significantly lower ($p=0.05$) entrapment yields than did 15-, 30-, and 45-min times, which did not differ from each other significantly. The particle size range of the prepared liposomes was evaluated using electron microscopy. Studies of liposomes contained in the first fraction after the void volume in gel filtration showed the presence of liposomes ranging from 0.1 to 2 µm in diameter. Successive fractions contained small-diameter liposomes, which remained in the circulation for extended periods. Entrapment techniques and separation procedures led to a liposome preparation with particles in the colloidal size range (0.001-0.5 µm). Dramatic differences in the orga
distribution of the liposome preparation in mice were produced when different particle size ranges were injected. Liposomes eluted in the first fraction after the void volume led to a maximum uptake by the liver and spleen 10 min after i.v. injection. Liposomes from pooled fractions provided less than half of the activity in the liver
as did the narrow size range liposome preparation
Investigations concerning improvement of the entrapment yield along with the production of a liposome product with an increased radioactive concentration are being planned. In addition, decreasing the labeling procedure time, which could lead to the development of a kit preparatio
suitable for human use, is being studied.

8073 RESOLVING BIOCHEMICALLY THE HEPATOCYTE' MULTIFUNCTIONAL PERICELLULAR MEMBRANE.

(Eng.) Evans, W. H. (Natl. Inst. Medical Res., Mill Hill, London, England). *Trends Biochem. Sci*
2(3):169-171; 1977.

Studies concerning the hepatocyte pericellular me
brane are reviewed. This membrane is complex and can be subfractionated to yield plasma membrane fractions from the blood sinusoidal, contiguous, and bile canalicular regions. The blood sinusoidal region is microvillar and accounts for 40-50% of surface area. Plasma membranes are vesicl
of density 1.11-1.14 g/cm^3 in sucrose and are rec
ered mainly from microsomal fractions; this regio
identified by perfusing the liver with ^{125}I-ligan
It has a high sialic acid and glycoprotein conten
The contiguous region accounts for 30-40% of surface area; here the plasma membranes are of densi
1.16-1.18 g/cm^3. Intercellular junctions are pre
Biochemical properties include a low glycoprotei
and glycolipid content and prominent gap-junctio
polypeptides; this region has the lowest specifi
activities of plasma membrane marker ecto-enzymes
The canalicular region is microvillar and account
for about 10% of surface area. These plasma membranes are isolated as canalicular complexes (den
sity 1.16-1.18 g/cm^3) or vesicles (density 1.13
This region has the highest specific activities
plasma membrane marker ecto-enzymes, cholesterol and sphingomyelin level. There is little activat
of adenylate cyclase by glucagon, and there is a high sialic acid and glycoprotein content. Seve
studies have indicated that radioactivity first associated with macromolecules at the hepatocyte'
Golgi apparatus is later found at the blood sinus
oidal region of the pericellular membrane. Thus, it may be assumed that plasma membrane glycoproteins, after their insertion into the blood sinus
oidal plasma membrane, can then redistribute late
ally. Such a mechanism would explain the lower concentration of glycoproteins generally in plas
membranes derived from the lateral region of cel
relative to membranes derived from microvillar a
brush border areas. However, a major unresolved problem concerns the extent to which plasma membrane specializations constrain lateral redistribution of components.

074 IDENTIFICATION OF ERYTHROPOIETIN PRODUCING CELLS IN FETAL MOUSE LIVER CUL-
URES. (Eng.) Gruber, D. F.; Zucali, J. R.; Mir-
nd, E. A. (Roswell Park Memorial Inst., 666 Elm
t., Buffalo, NY 14263). *Exp. Hematol.* 5(5):392-
98; 1977.

orphological studies were carried out to identify
he fetal hepatic cell responsible for the produc-
ion of erythropoietin in culture. Fetal mouse
iver explants produced measureable amounts of
rythropoietin in the culture media. Erythropoi-
tin was first detected in pooled medium between
ays 2 and 7 of culture; the amount increased with
ime and was greatest between days 15 and 21. The
ddition of anti-erythropoietin to the 15-21 day
ulture medium neutralized the erythropoiesis-
timulating capability of the culture. Immuno-
luorescent and carbon particle ingestion tech-
iques suggest that the erythropoietin is elaborated
 macrophages or Kupffer cells of the hepatic retic-
loendothelial system.

75 THE BIOCHEMICAL PREREQUISITES FOR PREVENTING PATHOGENIC LYSOLECITHIN ACTIVITY
 THE HUMAN GALLBLADDER. II. STUDIES ON THE SUB-
ELLULAR LOCALIZATION OF LYSOPHOSPHOLIPASE. (Eng.)
agesson, C.; Sjodahl, R. (Dept. Medical Micro-
iology, Univ. Linkoping, S-581 85 Linkoping, Swe-
en). *Scand. J. Gastroenterol.* 13(1):107-112;
978.

e subcellular localization of lysophospholipase
ctivity in the human gallbladder epithelium was
udied by differential and density gradient cen-
rifugation to determine whether the presence of
is enzyme could protect the gallbladder wall
gainst potentially pathogenic lysolecithin. Dif-
erential centrifugation revealed that lysophos-
olipase was enriched both in the lysosomal mito-
ondrial fraction (20,000 x *g* pellet) and in the
icrosomal fraction (100,000 x *g* pellet). The
ighest relative specific activity (2.27) was found
 the microsomal fraction, whereas most of the
zyme activity (56%) was recovered from the lyso-
mal mitochondrial fraction. The soluble frac-
ion (100,000 x *g* supernatant) contained only 6%
 the total activity. Although the cytosol did
t contain any significant lysophospholipase ac-
ivity, large amounts of enzyme were solubilized
ring sucrose density gradient centrifugation.
e findings suggest that a widespread subcellular
istribution of lysophospholipase in the gall-
ladder epithelium serves a physiologically favor-
le purpose. The authors suggest that one purpose
 to prevent the development of acute aseptic
olecystitis, but that this result is not achiev-
le in cases in which the gallbladder epithelium
 mechanically injured by an impacted stone.

76 THE BILIARY EXCRETION OF BUCOLOME IN THE RAT: A POSSIBLE CAUSE FOR CHOLERESIS.
Eng.) Kitani, K.; Nokubo, M.; Kanai, S.; Miura,
.; Uesugi, T. (Tokyo Metropolitan Inst. Gerontology, 35-2 Sakaecho, Itabashiku, Tokyo 173, Japan). *Biochem. Pharmacol.* 26(24):2457-2461; 1977.

Because the mechanism of bucolome (BC)-induced choleresis has not been elucidated, the possibility that BC or its metabolite(s) might induce osmotic choleresis when excreted into the bile was examined by measuring the extent of such excretion in anesthetized 10-week-old male Wistar rats. Following i.p. administration of ^{14}C-BC mixed with carrier BC (20 mg/100 g body weight), the common bile duct was cannulated, and seven successive 15-min bile samples were collected beginning 15 min after BC injection. In a second group of rats cannulation occurred before BC administration, and 15-min samples were collected for 2 hr. In both groups, a previously-cannulated femoral artery provided arterial blood samples at various intervals. The highest average plasma BC level was 0.47 mg/ml in group I rats and 0.3 mg/ml in group II rats. The total biliary excretion of BC (a percentage of the administered dose) was 19.0 ± 4.0 in group I rats and 24.5 ± 4.0 in group II rats from 15 min to 2 hr of sampling. A significant ($r=0.85$) linear relationship was observed between bile flow rate and the bile excretion rate of BC, 27 µl of bile being produced for each µmole of BC excretion. These results indicate that in rats BC excretion in bile could be a major cause of choleresis, possibly due to the osmotic force of the excreted BC. It is possible that, in animals without a bile fistula, the enterohepatic circulation of BC could maintain a higher plasma BC level than that encountered in this study.

8077 METABOLISM OF THE CARCINOGEN CHROMATE BY RAT LIVER MICROSOMES.
(Eng.) Gruber, J. E.; Jennette, K. W. (Dept. Chemistry, Dartmouth Coll., Hanover, NH 03755). *Biochem. Biophys. Res. Commun.* 82(2):700-706; 1978.

Studies were carried out to determine whether the oxidation state of chromium is affected in its metabolism by the rat liver microsomal systems, since the oxidation state of this element has been previously shown to be very important in determining the carcinogenicity and mutagenicity of chromium compounds and their effect on DNA synthesis. Incubation of chromate (4.0×10^{-4} M) with rat liver microsomes and 0.025 M NADPH resulted in reduction of hexavalent chromium to trivalent chromium. In the absence of NADPH, no reduction occurred. The amount of chromium reduced in the presence of NADPH depended on the concentration of the microsomes. With a microsomal protein concentration of 1.5 mg/ml, essentially complete loss of chromate was observed after 6 hr of incubation. Chromate reduction was also dependent on the concentration of NADPH. Maximum conversion to chromium III occurred at a NADPH concentration of 1.44×10^{-3} M upon incubation with 1.5 mg/ml microsomes for 6 hr. Time course studies at these concentrations showed that chromate was completely reduced to chromium III. Incubation of chromate with microsomes in the absence of NADPH led to complete recovery of chromate even after 24 hr incubation, indicating that chromate did not oxidize any components of the microsomal system under these conditions. In the absence of microsomes, less than 20% of the chromate was reduced by NADPH, compared with a greater than 98% reduction with NADPH and microsomes. These results suggest that an NADPH-requiring enzyme or enzyme system is involved in the *in vitro* metabolism of chromate. The results of this study, together with those of previous studies, suggest that chromium III may be the ultimate carcinogenic form of chromium.

8078 EFFECT OF EXPERIMENTAL MALNUTRITION ON CORTICOSTEROIDS AND LIVER CYTOPLASMIC RECEPTORS IN RATS.

(Eng.) Kadival, G. V.; Samuel, A. M. (Tata Memorial Hosp., Parel, Bombay 400 012, India). *Biochem. Med.* 18(3):353-359; 1977.

Adrenocortical function was studied in experimental malnutrition in male Wistar rats. Plasma corticosterone levels, liver cytosol binding capacity, and affinity binding constants were estimated in animals sacrificed on days 15, 21, and 28 after starting a low-protein (1% casein) diet. These parameters were also estimated in another group of animals that had been fed the low-protein diet for 4 weeks and were then given a normal diet; these animals were sacrificed on the 7th, 15th, and 21st days of repletion. Serum albumin levels declined markedly from control levels by the 15th day of the low-protein diet. Plasma corticosterone, liver cytosol binding capacity, and affinity constants for the cytosol binding protein remained unchanged during hypoalbuminemia and during replacement with the normal diet. Starvation was associated with hypertrophy of the adrenal glands, which was reflected by an increase in the weight of these glands. The weight returned to normal within 2 weeks on a normal diet. It is concluded that, even during progressive phases of malnutrition, the corticosteroid levels are maintained within normal limits, probably by a compensatory hypertrophy of the adrenal glands. The liver cytosol binding proteins are within normal limits and thus do not reduce the effectiveness of the biological action of corticosteroids.

8079 EFFECTS OF HEPATOTOXIC AGENTS ON HEPATIC MICROSOMAL METABOLISM OF ESTROGENS IN THE RAT.

(Eng.) Lopez del Pino, V.; Bolt, H. M. (Institut fur Toxikologie der Universitat Tubingen, Wilhelmstr. 56, D-7400 Tubingen 1, W. Germany). *Arzeim. Forsch.* 27(11):2117-2120; 1977.

The effects of carbon tetrachloride- and ethanol-induced liver damage on the activities of the microsomal enzymes involved in estrogen metabolism were investigated in the livers of male Wistar rats. The animals were treated with ethanol, either acutely (6 ml/kg, p.o., and a 40% volume/volume aqueous solution) or chronically (20% volume/volume ethanol in drinking water for 100 days), or with CCl_4 (2.5 or 5 ml/kg of a 50% solution, p.o.); in further experiments rats received a single dose of thioacetamide (100-300 mg/kg). Acute or chronic ethanol pretreatment had no effect on the levels of liver microsomal cytochrome P-450, but acute and chronic treatment significantly reduced NADPH-cytochrome c reductase activity ($0.0125>p>0.01$) in comparison with control levels. Acute treatment decreased mestranol demethylation significantly ($0.01>p>0.00$ and chronic treatment decreased demethylation even further ($p<0.0005$). Acute or chronic ethanol trea ment had no effect on the aromatic hydroxylation o estradiol, as indicated by microsomal replacement of tritium from 2,4,6,7-^{3}H-estradiol. More severe liver damage by CCl_4 or thioacetamide was associat with a reduction in microsomal cytochrome P-450 ($0.01>p>0.005$ and $0.0025>p>0.0005$ for 2.5 and 5.0 kg CCl_4 doses, resp.; $0.05>p>0.025$ and $0.0025>p>0.$ for various thioacetamide doses), whereas NADPH-cytochrome c reductase was not significantly dimin ished. Demethylation of mestranol was significant inhibited by 2.5 and 5.0 ml/kg CCl_4 ($0.0125>p>0.01$ and $0.05>p>0.025$, resp.), as was aromatic hydroxyl tion of estradiol ($0.05>p>0.025$ and $0.0025>p>0.000$ resp.). Although chronic thioacetamide treatment has been previously reported to decrease microsoma aromatic estrogen hydroxylation, a single dose (20 or 300 mg/kg) caused increased microsomal formatio of estrone from estradiol ($0.0025>p>0.0005$ or 0.00 $p>0.0025$, resp.), which is regarded to be a more lipophilic substrate for the microsomal estrogen 2 hydroxylase than is estradiol. These data show t hepatotoxic agents may act differentially on hepatic metabolism of endogenous steroids.

8080 PATHWAYS OF ETHANOL OXIDATION IN HEPATIC MICROSOMES OF ACATALASEMIC (Csb) MICE.

(Eng.) Vatsis, K. P.; Schulman, M. P. (Univ. Illinois Medical Center, Chicago, IL 60612). *Adv. Exp. Med. Biol.* 85A:303-317; 1977.

A previous study suggesting that NADPH-dependent ethanol oxidation by hepatic microsomes (MEOS) is independent of catalase activity was reinvestigated using the same techniques in genetic control (Csa) and acatalasemic (Csb) mice. Csa a Csb microsomes kept in an ice bath at 0-4 C and s sequently incubated at 25 C or 30 C for 10 min showed identical MEOS and catalase activities, whereas incubation of similar preparations at 37 for 10 min led to a 20-35% loss of catalase and a 10-30% decrease in MEOS activities of Csb as compared with corresponding activities in Csa mice. Based on these observations, MEOS assays were uniformly carried out at 30 C (10 min), regardles of microsomal origin or pretreatment. Preincubation of Csb microsomes at 42-44 C for 15 min resulted in 97-99% inactivation of catalase activit and a concomitant 60-70% loss of MEOS activity; neither the catalase nor MEOS activity of Csa microsomes was affected by this procedure. Preincubation at 43 C for 15 min had no effect on NADPH-linked drug-metabolizing activities of Csa or Csb microsomes. MEOS activity of "zero-time" microsomes from either strain, or of 43 C-preincubated Csa microsomes, was inhibited 40% by 0. mM propylpyrazole, a potent inhibitor of alcohol dehydrogenase. Due to the presence of peroxidatically-uncoupled catalase in 43 C-preincubated

Csb microsomes, residual MEOS activity in these preparations was unaffected by 0.1 mM cyanide or azide, but was totally obliterated by 0.03 mM propylpyrazole. In contrast, the same concentration of propylpyrazole produced only a 10% inhibition of NADPH-dependent aniline p-hydroxylation and aminopyrine, ethylmorphine, and benzphetamine *N*-demethylation activities of "zero-time" or of 43 C-preincubated microsomes from either strain. Incubation of Csb microsomes for 10 min at 37 C or 30 C resulted in catalase activities that were 72% and 102%, resp., of those obtained with similarly incubated Csa microsomes. Furthermore, incubation of Csb microsomes at 37 C (10 min) with ethanol and 0.5 or 5.0 μg/ml glucose oxidase gave rise to ethanol oxidation rates that were 65% and 30%, resp., of corresponding values obtained with Csa microsomes. Clearly, inactivation of catalase in Csb microsomes during 37 C incubations causes a shift in the H_2O_2/catalase ratio to higher values, leading to a disproportionately larger contribution of the "catalatic" reaction and a greater inhibition of ethanol oxidation at 5.0 as opposed to 0.5 μg/ml glucose oxidase. In contrast, no differences in ethanol oxidation rates were observed between Csa and Csb microsomes incubated at 30 C (10 min), regardless of glucose oxidase concentration. These studies indicate strongly that hepatic MEOS activity can be accounted for by the concerted action of catalase (60-70%) and alcohol dehydrogenase (30-40%).

8081 METABOLISM OF ALCOHOL AT HIGH CONCENTRATIONS: ROLE AND BIOCHEMICAL NATURE OF THE HEPATIC MICROSOMAL ETHANOL OXIDIZING SYSTEM.

(Eng.) Teschke, R.; Matsuzaki, S.; Ohnishi, K.; Masumura, Y.; Lieber, C. S. (Veterans Admin. Hosp., Bronx, NY 10468). *Adv. Exp. Med. Biol.* 85A:257-280; 1977.

Studies concerning the role and biochemical nature of the hepatic microsomal ethanol oxidizing system (MEOS) are reviewed, and results of the authors' xperiments are presented. At intermediate nd higher alcohol concentrations, ethanol metabolism proceeds via alcohol dehydrogenase (ADH) nd MEOS, whereas catalase plays no significant role. Following prolonged ethanol consumption, n enhancement of both MEOS activity and the rates of ethanol metabolism occurs; the latter persists espite inhibition of ADH by pyrazole and catalase y sodium azide, suggesting that MEOS is involved n the adaptive increase. This conclusion was upported by the authors' experiments in which utanol had no inhibitory effect on *in vitro* oxiation of ethanol mediated by catalase in the presence of a H_2O_2-generating system. In liver lices, the pyrazole-insensitive ethanol oxidaion was decreased by 43.2% ($p<0.01$) in the presnce of butanol, a value similar to the correspondng result obtained in isolated microsomes for he inhibition of MEOS. These results suggest hat the MEOS is responsible for the pyrazole-nsensitive pathway. Other experiments in which minotriazole pretreatment failed to inhibit thanol metabolism provided strong evidence against a significant involvement of catalase in ethanol metabolism under physiological conditions in which no DL-alanine was added. MEOS exhibits characteristics similar to those of other microsomal drug metabolizing enzymes and can be differentiated and isolated from both ADH and catalase activities. Reconstitution of MEOS activity was achieved with partially purified cytochrome P-450 and NADPH-cytochrome c reductase in the presence of synthetic phospholipid. The results of the present studies and others in the literature have led to the acceptance of the previously proposed thesis that MEOS is responsible for a major part of the adaptive increase in ethanol metabolism following chronic ethanol consumption and that the microsomal system is a distinct mechanism capable of oxidizing various alcohols by a pathway not requiring catalase or ADH.

8082 ALCOHOL METABOLISM AT HIGH ALCOHOL CONCENTRATIONS.

(Eng.) Thieden, H. I. D; Quistorff, B.; Grunnet, N. (Dept. Biochemistry A, Panum Inst., Univ. Copenhagen, DK-2200 Copenhagen, Denmark). *Adv. Exp. Med. Biol.* 85A:247-255; 1977.

The incorporation rate of tritium from (R,S)ethanol-1-^{3}H, (R)ethanol-1-^{3}H, and (S)ethanol-1-^{3}H in lactate and β-hydroxybutyrate was investigated by gas-liquid chromatography to estimate the extent of participation of alcohol dehydrogenase in ethanol oxidation at high concentrations of ethanol and to determine the intracellular location of acetaldehyde oxidation. In rat hepatocyte cultures containing 3 mM pyruvate in which 65 mM (R,S)ethanol-1-^{3}H was used as substrate, the labeling rate of lactate declined with time. The rate declined with the decrease in pyruvate concentration in the incubation medium and the concomitant fall in lactate production. The tritium incorporation rate into lactate was decreased from 1.5 μmol/min/ml packed cells to 0.23 μmol/min/ml in the presence of 4-methylpyrazole. In these experiments, the alcohol dehydrogenase-mediated ethanol oxidation rate was 3.18 ± 0.19 μmol/min/g wet weight, indicating that less than 20% of the acetaldehyde is oxidized in the cytoplasm. Using (R)ethanol as substrate, a constant fraction of tritium was incorporated into lactate, indicating that this incorporation is proportional to the formation of ^{3}H-NADH in this compartment. Tritium incorporation into lactate from (R)ethanol did not decrease when the ethanol concentration was increased from 6 mM to 65 mM. Providing the same isotope effect is present at high and low ethanol concentrations, the latter result implies that no substrate inhibition of alcohol dehydrogenase activity occurs in liver cells. Alternatively, a shift in the isotope effect could occur at high ethanol concentrations.

8083 ETHANOL METABOLISM, OXYGEN AVAILABILITY AND ALCOHOL INDUCED LIVER DAMAGE.

(Eng.) Israel, Y.; Kalant, H.; Khanna, J. M.; Orrego, H.; Phillips, M. J.; Stewart, D. J. (Dept. Pharmacology, Univ. Toronto, Ontario M5S 1A8, Canada). *Adv. Exp. Med. Biol.* 85A:343-358; 1977.

Studies concerning ethanol metabolism, oxygen availability, and alcohol-induced liver injury are reviewed. The rates of ethanol oxidation in various species are linked to the rates of general metabolism, and more specifically that of O_2 utilization by the liver. After chronic ethanol administration, increased oxidation of ethanol is accompanied by increased total hepatic O_2 utilization, as studied in the whole animals, the perfused liver, and isolated liver slices. The correlation is particularly striking in the spontaneously hypertensive rat. The linkage of these two phenomena makes the livers of rats chronically consuming ethanol abnormally vulnerable to hypoxic damage. Exposure to a 5% oxygen atmosphere for 6 hr produced major elevations of SGOT and serum ornithine-carbamyl transferase activities and marked centrilobular necrosis in alcohol-treated animals but not in controls. The same differential susceptibility was found to acute anemia produced by bleeding. These data indicate that chronic ethanol administration increases the susceptibility of the liver to ischemic injury.

8084 METABOLISM OF 25-HYDROXYLATED BILE ALCOHOLS. (Eng.) Mosbach, E. H.; Salen, G.; Shefer, S. *In : Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* (Baltimore: University Park Press): 11-15; 1977.

Studies concerning 25-hydroxylated bile alcohol metabolism are reviewed. Patients with the sterol storage disease cerebrotendinous xanthomatosis (CTX) secrete 25-hydroxylated bile alcohols in bile and feces. Quantitatively, the predominant bile alcohols are 5β-cholestane-3α,7α,12α,25-tetrol, 5β-cholestane-3α,7α,12α,23β,25-pentol, and 5β-cholestane-3α,7α,12α,24α,25-pentol. CTX patients produce cholic acid from cholesterol mainly via the intermediate 5β-cholestane-3α,7α,12α,25-tetrol, while chenodeoxycholic acid is formed probably via 5β-cholestane-3α,7α,25-triol. Nevertheless, subjects with CTX have the capacity to transform a 26-hydroxylated bile alcohol, 5β-cholestane-3α,7α,26-triol into cholic acid and chenodeoxycholic acid. Experiments *in vitro* indicate that hepatic microsomal enzymes of CTX patients, rat, and man catalyze the hydroxylation of 5β-cholestane-3α,7α,12α,25-tetrol in the 24α and 24β position, in the presence of O_2 and NADPH. However, only 5β-cholestane-3α,7α,12α,24β,25-pentol is converted to cholic acid (plus acetone) by soluble hepatic enzymes. This transformation requires NAD and probably involves a 24-ketone as an intermediate.

8085 ACETALDEHYDE METABOLISM IN VIVO DURING ETHANOL OXIDATION. (Eng.) Eriksson, C. J. P. (Res. Lab. State Alcohol Monopoly, Box 350, SF-00101 Helsinki 10, Finland). *Adv. Exp. Med. Biol.* 85A:319-341; 1977.

Information concerning acetaldehyde (AcH) metaboli
during ethanol oxidation is reviewed. The liver
the primary site for the oxidation of ethanol-derived AcH in the rat. Only a small amount of the
total AcH formed in this organ escapes into the
rest of the body, but this amount increases with
increasing hepatic ethanol concentrations. The bu
of the hepatic AcH output is eliminated extrahepatically, thus drastically changing the AcH le
from that initially leaving the liver. Nevertheless, the extrahepatic blood AcH levels can be us
as relatively accurate indicators of the correspo
ing hepatic AcH levels, since they are highly correlated with them. Significant levels of brain A
occur only at very high arterial blood AcH concentrations.

8086 THE ACUTE EFFECTS OF ETHANOL ON LIVER
BRAIN TRYPTOPHAN METABOLISM. (Eng.)
Badawy, A. A. B.; Evans, M. (Witchurch Hosp., Ca
diff, CF4 7XB, Wales). *Adv. Exp. Med. Biol.* 85A
559-569; 1977.

The effects of acute ethanol administration on l
and brain tryptophan metabolism are reviewed. E
anol enhances the activity of rat liver tryptoph
pyrrolase by increasing the availability of circulating free tryptophan to the liver by catecholamine-mediated lipolysis followed by displac
ment of protein-bound serum tryptophan. The response of the mouse liver enzyme to ethanol is
strain-dependent; ethanol activates the enzyme i
CBA/CA but not in C57/BL mice. Ethanol exerts a
biphasic effect on the concentrations of rat bra
tryptophan, 5-hydroxytryptamine, and 5-hydroxyindole-3-yl-acetic acid. Both aspects of this b
phasic effect are associated with an altered ava
ability of circulating free tryptophan. The ini
tial enhancement by ethanol of brain tryptophan
metabolism may be due to the above mentioned lip
lytic mechanism, whereas the subsequent decrease
in brain indoles may be caused by the enhanced
tryptophan pyrrolase activity. Brain tryptophan
metabolism is decreased by ethanol in CBA/CA mic
whereas no such change is observed in C57/BL mic

8087 EFFECT OF THE COENZYMES UDP-Glc, CDP-C
SAM AND CoA-SH ON THE LIVERS OF RATS
TREATED WITH ETHANOL AND A HIGH-FAT DIET. (Fre.
Cascales, M.; Feijoo, B.; Cerdan, S.; Robles-Chi
lida, E. M.; Santos-Ruiz, A. (Universidad Complu
tense, Madrid, Spain). *Ann. Pharm. Fr.* 35(11/1
447-459; 1977.

The protective effect of the lipotropic substan
uridine-diphosphoglucose (UDP-Glc), S-adenosylm
ionine (SAM), cytidine-diphosphocholine (CDP-Ch
and coenzyme A (CoA-SH) against development of
liver in rats fed ethanol and a high-fat diet w
investigated. Rats were given either ethanol (
in the drinking water) and a diet composed of 4
vegetable fat or a normal diet without ethanol.
Half the rats on the high-fat diet with ethanol
injected i.p. daily with 30 mg/kg UDP-Glc, 1.5
kg CDP-Ch, 3 mg/kg SAM, and 0.1 mg/kg CoA-SH, w

s the other half (controls) were injected daily with
n identical volume of physiological saline solu-
ion. At the end of 3 months, the rats were killed,
nd their livers were weighed, examined histologi-
ally, and their content of oxidoreductive and urea
ycle enzymes determined. Differences in the ratio
f liver weight/body weight in treated and untreated
ats on the ethanol and high-fat diet were not
ignificant. Untreated rats on the ethanol and
igh-fat diet had fatty livers. Ultrastructural
tudy of the livers of rats on the high-fat with
thanol diet showed a marked decrease (from 46% to
%) in the number of hepatocytes with fatty vacuoles
n rats treated with lipotropic substances compared
ith the untreated rats; in the treated rats, fatty
epatocytes were found grouped around the blood
essels. Of the liver oxidoreductive enzymes whose
evels were significantly ($p<0.05$-0.001) reduced
lucose-6-phosphate dehydrogenase, 6-phosphogluco-
ate dehydrogenase [6PGDH], transaldolase, and
ocitrate dehydrogenase NADP) by the high fat and
hanol regime, only the 6PGDH level was significant-
($p<0.05$) restored by the protective treatment.
the urea cycle enzymes whose levels were signifi-
ntly ($p<0.05$-0.001) reduced (carbamyl-phosphate
nthetase [CPase], ornithine transcarbamylase, and
ginase) by the high-fat and ethanol diet, CPase
d arginase were significantly ($p<0.01$) restored by
eatment. Liver GOT and glutamate dehydrogenase
vels were decreased in rats on the high-fat and
hanol diet ($p<0.05$-0.001); however, administration
the lipotropic agents significantly ($p<0.05$) pre-
nted the decrease of GOT. The lipotropic agents
so appeared to prevent the accumulation of free
monia in the livers of rats on the high-fat and
anol diet.

88 THE EFFECT OF PURINE BASES AND NUCLEOTIDES ON ETHANOL-INDUCED FATTY LIVER SYNDROME.

g.) Auditore, J. V.; Crisona, F.; Patthey, H.;
intonwa, A. (Meharry Medical Coll., Nashville,
37208). *Arch. Int. Pharmacodyn.* 232(2):302-
; 1978.

capacity of the purine bases and their nucleo-
le derivatives to prevent chronic ethanol-induced
ty liver and depressed adenine nucleotide levels
investigated in female Sprague-Dawley rats.
mean liver triglyceride concentration in rats
a control diet (12.3 ± 1.1 mg/g wet weight
er) was significantly lower ($p<0.001$) than that
rats fed either a control liquid fat diet (23.9
.1 mg/g), a fat diet plus adenine as 0.1% of
t (20.1 ± 1.8 mg/g), a fat diet plus 0.1% ATP
.8 ± 2.0 mg/g), a fat diet plus 0.1% guanine
.0 ± 1.6 mg/g), a fat diet plus 0.1% GTP (24.0
.9 mg/g), a fat diet plus ethanol as 20% of
oric intake (72.0 ± 5.1 mg/g), a fat diet plus
anol with or without adenine (43.7 ± 6.2 mg/g),
at diet plus guanine plus ethanol (70.1 ± 4.8
g), a fat diet plus ATP plus ethanol (68.6 ±
mg/g), or a fat diet plus GTP plus ethanol
.1 ± 5.3 mg/g). The hepatic ATP levels were
nificantly lower in animals fed the fat diet
70 ± 0.06 μmol/g wet weight liver) than in those
the control diet (2.96 ± 0.08 μmol/g). Ethanol
ne depressed the hepatic ATP level more than 85% of normal, and the level in the animals fed the fat diet plus ethanol alone (1.48 ± 0.8 μmol/g) was significantly reduced compared with the levels in animals fed control diet, fat diet, fat diet plus adenine (2.80 ± 0.08 μmol/g), fat diet plus ATP (2.76 ± 0.05 μmol/g), fat diet plus guanine (2.67 ± 0.09 μmol/g), fat diet plus GTP (2.60 ± 0.10 μmol/g), or fat diet plus ethanol plus adenine (2.32 ± 0.12 μmol/g). The incorporation of adenine into the fat diet partially restored hepatic ATP levels, and a slight increase was observed with ATP in the diet, but these differences were not statistically significant. Guanine and GTP failed to restore normal ATP levels.

8089 STUDIES ON FATTY LIVER WITH ISOLATED HEPATOCYTES. I. THE ACTION OF COLCHICINE, PHALLOIDIN, CYTOCHALASIN B, AND CYCLOHEXIMIDE ON PROTEIN AND TRIGLYCERIDE SYNTHESIS AND SECRETION.

(Eng.) Gravela, E.; Poli, G.; Albano, E.; Dianzani, M. U. (Istituto di Patologia Generale, Corso Raffaello 30, 10125 Torino, Italy). *Exp. Mol. Pathol.* 27(3):339-352; 1977.

The effects of colchicine, phalloidin, cytochalasin B, and cycloheximide on protein and triglyceride synthesis and secretion were studied in isolated rat hepatocytes to investigate the role of derangement of contractile protein systems in the pathogenesis of fatty liver. Control cells and cells treated with 20 μM colchicine or cycloheximide were completely dissociated from each other and demonstrated intact cell membranes. Five minutes after the addition of 20 μM cytochalasin B, plasma membranes showed numerous bubbles and many hepatocytes formed clusters of 4-10 cells. Similar changes were seen with 20 μM phalloidin, but these occurred less rapidly (after about 60 min). Colchicine (10 μM) produced 35% inhibition of protein secretion after 60 min of incubation; after 90 and 120 min, it reached about 60-65% inhibition. Cycloheximide (0.7 μM) produced a 20% decrease in protein secretion after 30 min, and a 40% decrease was noted after 60 min; inhibitions after 90 and 120 min were 55% and 60%, resp. Phalloidin (20 μM) had no effect on protein secretion after 30 min but provoked 50-60% inhibition at 60-120 min. While cytochalasin B (20 μM) did not significantly inhibit protein secretion after 30 min, about 50% inhibition occurred after 60 min; inhibition decreased slightly thereafter. Colchicine (10 μM) inhibited lipoprotein triglyceride secretion by about 60% at 30 min. Cycloheximide (0.7 μM) had no effect at 30 min but inhibited triglyceride secretion by 40% after 60-120 min. Phalloidin (20 μM) inhibited triglyceride secretion by 35% after 30 min, by 50% after 60 and 90 min, and by 40% by 120 min. Cytochalasin B (20 μM) did not modify triglyceride secretion at any time. There was a good quantitative correspondence between the decrease in secreted triglyceride radioactivity and the increase in intracellular triglyceride radioactivity, indicating that colchicine, cycloheximide, and phalloidin produced *in vitro* liver steatosis. The substances studied did not significantly modify triglyceride synthesis. The results show that protein and lipoprotein secretion from isolated liver cells may be blocked in at least two ways: (a) by inhibition of protein synthesis and (b) by impairment of the microtubular system.

8090 D-GALACTOSAMINE INDUCED HEPATIC CIRRHOSIS: ITS ULTRASTRUCTURAL AND BIOCHEMICAL STUDIES IN RAT. (Eng.) Funatsu, K.; Ishii, H.; Shigeta, Y.; Morita, A.; Tsuchiya, M. (Sch. Medicine, Keio Univ., Shinjuku-ku, Tokyo 160, Japan). *Acta Hepatogastroenterol.* 25(2):97-104; 1978.

Ultrastructural and biochemical studies of the liver were carried out in female Wistar rats treated with D-galactosamine (GALN, 250 mg/kg, i.p.) for 7 months. Histological examination of liver specimens taken at the end of treatment showed cirrhotic changes in most animals. Ultrastructural study showed mitochondrial proliferation and crenation of the mitochondrial membranes, focal hypertrophy of the smooth endoplasmic reticulum, saccular dilatation of the rough endoplasmic reticulum, the absence of liposomes in dilated tubules of the smooth endoplasmic reticulum, and smooth scattered fat droplets in the cytoplasm. No large fat droplets were observed in the cytoplasm. The nucleolous was relatively well-preserved, contrasting with the fact that marked fragmentation or small spherical deformities of the nucleoli are characteristic of GALN-induced liver injury. Proliferation of collagen fibers was present around the hepatocytes, and ruthenium red-positive material was found in the spaces of Disse and in part of the sinusoids. Liver weight increased significantly ($p<0.01$) after GALN treatment. However, the total lipid, triglyceride, and phospholipid concentrations were not affected by the treatment. There was a significant decrease in microsomal protein concentration after treatment ($p<0.005$) and an increase in the cytochrome P450 content ($p<0.05$). The plasma albumin concentration was significantly decreased after treatment ($p<0.01$), and the value of the zinc turbidity test was increased ($p<0.05$). There was no change in the SGPT level or in the total cholesterol concentration. Since there was no change in the contents of total hepatic lipids, triglycerides, proteins, or phospholipids, the increased liver weight after GALN treatment may be due to an increase in the amount of liver collagen fibers. It is unlikely that chronic GALN administration produces smooth endoplasmic reticulum hypertrophy in the rat liver, since there was no significant change in the microsomal phospholipid concentration and since the microsomal protein content was decreased.

SECRETION AND METABOLISM

Intestine

114 USE OF THE CONSTANT PERFUSION TECHNIQUE IN THE NONSTEADY STATE. (Eng.) Levitt, . D.; Bond, J. (Section Gastroenterology, Box 346 ayo, Univ. Minnesota, Minneapolis, MN 55455). *astroenterology* 73(6):1450-1453; 1977.

e source and magnitude of errors that may occur in measurements during nonsteady-state perfusion (e.g., gallbladder or gastric emptying) are presented. Errors arise (1) when the aliquots taken from two compartments of unequal volume are pooled for analysis but were not proportional in size to their respective compartment volumes (the total volume of the two compartments is underestimated; the error is nearly 50% when one compartment exceeds the other by a factor of 5 in volume), (2) when aliquots aspirated intermittently at a constant rate from a compartment of inherently fluctuating volume are pooled for analysis (if the volume changes instantaneously by a factor of 5, there is the same error and magnitude as in [1] above), (3) when the error committed in (2) is exacerbated by measuring the infusate volume as well (the underestimation in [1] is increased to >80%), (4) when one fraction of the aspirate has a higher marker concentration than does the remainder of the aspirate due to variations in the flow rate of perfusate and the fractions are pooled for analysis (if the marker concentrations is overestimated, then the true flow rate will be underestimated and vice versa, the magnitude of the error depending on the fluctuation of the marker concentration in the system and the relation of the aspiration rate to the true flow rate), (5) if a higher concentration of solute exists during periods of high flow and samples from different flow periods are pooled for analysis (the concentration of the solute and, hence, its absorption or secretion flow rate, is underestimated to an even greater extent than is volume), and (6) if a lower concentration of solute is present during periods of high flow and the samples are pooled for analysis (the marker concentration is overestimated, but the underestimation of volume flow reduces the error in the calculated total solute flow rate). Under nonsteady-state conditions, analysis of repeated small aliquots of aspirate would provide some information on the magnitude of the error, although precise calculation is impossible unless the fraction of perfusate aspirated is known. When constant-rate aspiration introduces error into the measurement of the flow rates of solutes not in the perfusate, the fastest feasible infusion rate should provide the most accurate result; if infusion must be slow, short-interval aspiration will reduce error. Also, the maximum possible quantity of perfusate should be collected as opposed to aspiration at a fixed rate. Two situations where a correct estimate of solute flow may be obtained despite nonsteady conditions are (1) if the test solute enters and is absorbed into the test segment at a constant rate independent of volume flow and (2) if the marker concentration is constant but solute concentration fluctuates.

8115 CHRONIC ALCOHOL CONSUMPTION DOES NOT MODIFY CHOLECYSTOKININ BLOOD LEVELS ESTIMATED BY BIOASSAY IN THE DOG.

(Eng.) Planche, N. E.; Chau-Huu, T.; Lai, P. P.; Sarles, H. (Unite de Recherches de Pathologie Digestive, Inserm U-31, 46, chemin de la Gaye, F-13009, Marseilles, France). *Digestion* 16(1/2):194-198; 1977.

To examine the hypothesis that increased pancreatic protein secretion in chronic alcoholism is due to increased cholecystokinin (CCK) release, blood levels of CCK were measured by an *in vitro* rabbit gallbladder bioassay in two series of dogs: five that received 2 g/kg 45% ethanol/day for 12-18 months via a gastric cannula and five controls. There was no difference in CCK activity between the two groups, either in the fasting state, after intragastric administration of ethanol, or after intraduodenal administration of 20 ml oleic acid following the infusion of secretion (1 clinical U/kg/hr, i.v., for 1 hr). CCK release is not modified during the course of chronic alcohol intoxication in the dog, and, therefore, differences in CCK release do not play a part in increased pancreatic protein secreti in chronic alcoholic dogs.

8116 TRANSFER AND METABOLISM OF CITRATE, SUCCINATE, α-KETOGLUTARATE AND PYRUVATE BY HAMSTER SMALL INTESTINE.

(Eng.) Browne, J. L.; Sanford, P. A.; Smyth, D. H. (Middlewood Hosp., Sheffield, England). *Proc. R. Soc. Lond.* [*Biol.*] 200(1139):117-135; 1978.

The transfer of citrate, succinate, α-ketoglutarat and pyruvate was studied in everted sacs of hamste small intestine to determine specific transfer mechanisms for each of these. All four intermediates were rapidly removed from the mucosal fluid (14.0, 11.7, 8.9, and 9.2 μmol/hr for succinate, α-ketoglutarate, citrate, and pyruvate, resp.) and appeared in the serosal fluid in the presence of metabolites. Only in the case of citrate, where consistently high recoveries of the unchanged intermediate were obtained, was there chromatographic evidence for transfer against a concentration gradient. The inhibitory effects of several carboxylates, some of which are not intermediates of the citric acid cycle, were teste All the dicarboxylates tested (succinate, α-ketoglutarate, fumarate, oxaloacetate, glutarate, and malate, all at 7.5 mM), with the exception of the latter two, were potent inhibitors (by >70%) of citrate transfer. Tricarballylate and pyruvate (both 7.5 mM) also produced significant inhibitio (69% and 26%, resp.), but the inhibition produced by 7.5 mM *cis*-aconitate was insignificant. The dicarboxylates produced inhibitions of succinate transfer that were significant at the 5% level, although less than the inhibitions produced on citrate transfer (5-82%). The 5% inhibition seen with glutamate was the only insignificant inhibition. Citrate, tricarballylate, and pyruvate reduced transfer by 54%, 59%, and 36%, resp., all significant at the 5% level; the effect of *cis*-aconitate was again insignificant. A similar pattern of inhibition of α-ketoglutarate transfer was seen, in that the effects of the dicarboxylates were greatest while the effect of pyruvate was least. These results suggest that carboxylates compete at the luminal membrane for the mechanisms involved in citrate, succinate, and α-ketoglutarate transfer, and that the mechanism for the transfer of these intermediates is different from the pathway involved in pyruvate transfe The transfer processes for citrate and succinate were saturable, and more than one pathway may be involved in the transfer of succinate. Pyruvate showed little interaction with the other three intermediates. A saturable component of transfe was demonstrated, although diffusion contributed considerable proportion of the total transfer.

portance of a downhill sodium gradient for trans-
r of citrate, succinate, α-ketoglutarate, and
ruvate across the luminal membrane was estab-
shed. A number of carboxylates stimulated the
tential differences across the intestine, al-
ough this was different from the potential dif-
rence produced by sugars and amino acids.

17 INFLUENCE OF ANTIBIOTICS ON MICROBIAL
INTESTINAL TRANSFORMATION OF CHOLESTEROL
COPROSTANOL IN MAN. (Eng.) Midvedt, T.; Fred-
ichsen, P. (Kaptein W. Wilhelmsen og Frues Bak-
riologiske Institutt, Univ. Oslo, Oslo, Norway).
and. J. Gastroenterol. 12(6):669-672; 1977.

e fecal excretion of coprostanol was studied in
healthy volunteers receiving antibiotics to in-
stigate the role of intestinal bacteria in the
nversion of cholesterol to coprostanol. The
llowing antibiotics were used: doxycycline (4
ojects), oxitetracycline (3), ampicillin (3),
enoximethylpenicillin (3), clindamycin (3), neo-
cin sulfate (1), and bacitracin (2). Before
tibiotic administration, coprostanol excretion
r exceeded that of cholesterol in all but one
oject. Antibiotic administration reduced the
prostanol/cholesterol ratio to less than 1 in
cases except subjects treated with doxycycline
roughout a 3-week observation period. In sub-
cts that received phenoximethylpenicillin, the
io went below 1 the day after administration of
drug was discontinued in one of the three men
estigated, increasing to 3.0 and 6.9, resp.,
nd 2 weeks later. In subjects receiving clinda-
in, ampicillin, or tetracycline, no coprostanol
detected on the first day, and in two of them,
duction of coprostanol was absent even after 12
15 weeks, resp. These results show that four
six antibiotics tested have a marked influence
microbial intestinal cholesterol transformation
coprostanol. Further studies are required to
ermine whether an antibiotic-induced absence of
estinal coprostanol production may have an in-
ence on other aspects of cholesterol metabolism.

8 HORMONAL STIMULATION OF INTESTINAL BRUSH
BORDER ENZYMES RELEASE. (Eng.) Eloy, R.;
ltier, J. P.; Raul, F.; Mirhom, R.; Clendinnen,
Grenier, J. F. (Unit 61 INSERM, Surgical Res.
Biophysiopathology of the Intestine, Avenue
iere, F-67200 Strasbourg, France). *Res. Exp.*
. (Berl.) 172(2):109-121; 1978.

importance of intestinal brush border enzyme
ease in response to graded doses of glucagon,
tagastrin, and cerulein was studied in rats
er common bile duct and pancreatic duct ligation.
intraluminal release of sucrase, alkaline
sphatase, aminopeptidases, and enterokinase was
reased after the *in vivo* administration of any
of the hormones at doses ranging between 10 pg
2 μg, with some changes reaching significance
.005-0.05). *Ex vivo* perfusion with glucagon
g) significantly increased the activities of
ase ($p<0.005$), alkaline phosphatase ($p<0.01$),
aminopeptidase ($p<0.05$) above control values.

Ex vivo perfusion with 20 or 200 pg pentagastrin significantly elevated the activities of sucrase, alkaline phosphatase, and aminopeptidase above control levels ($p<0.005-0.05$ at various times). The *ex vivo* administration of cerulein (100 pg) significantly stimulated sucrase, alkaline phosphatase, and aminopeptidase activities ($p<0.005-0.05$). The results suggest that there is a direct hormonal stimulation of the intestinal mucosa. This effect might be mediated, at least in part, by cyclic AMP, since 2 mM dibutyryl cyclic AMP exerted a marked stimulatory effect on the intraluminal release of proteins, sucrase, and enterokinase; however, the enzyme pattern following this stimulation was different from that produced by the three hormones.

8119 FOLATE CONJUGASE: TWO SEPARATE ACTIVITIES IN HUMAN JEJUNUM. (Eng.) Reisenauer, A. M.; Krumdieck, C. L.; Halsted, C. H. (Dept. Internal Medicine, Univ. California, Davis, CA 95616). *Science* 198(4313):196-197; 1977.

Folate conjugase activity from jejunal segments obtained at surgery in obese patients undergoing jejuno-ileal bypass was assayed using cell fractionation and diethylaminoethyl (DEAE)-cellulose and gel chromatography. On the basis of pH optima, inhibition by *p*-hydroxymercuribenzoate (PHMB), and molecular weight, two separate jejunal mucosal folate conjugase activities were found. One enzyme activity, membrane-bound and concentrated in the brush border fraction, was found to have an approximate molecular weight of 91,000 daltons, a neutral pH optimum, and no apparent requirement for sulfhydryl groups in the active site, since it was not inhibited by PHMB. The second enzyme activity was soluble and intracellular, had an approximate molecular weight of 45,000 daltons, an acid pH optimum, and an apparent requirement for sulfhydryl groups, since it was completely inhibited by PHMB. Although certain characteristics of the brush border and supernatant folate conjugase activities may have been altered by detergent treatment, nevertheless, prior to Triton solubilization, the brush border and supernatant fractions obtained by centrifugation exhibited distinct differences with regard to pH optima and PHMB inhibition. Although precise localization was not attempted, it is probable that the intracellular activity represents previously described lysosomal folate conjugase. Folate conjugase in the brush border may accomplish the initial digestion of dietary pteroylpolyglutamates.

8120 TOPOGRAPHICAL STUDIES ON INTESTINAL MICROVILLOUS LEUCINE β-NAPHTHYLAMIDASE ON THE OUTER MEMBRANE SURFACE. (Eng.) Takesue, Y.; Nishi, Y. (Res. Inst. Environmental Medicine, Nagoya Univ., Nagoya, Aichi 464, Japan). *J. Membr. Biol.* 39(4): 285-296; 1978.

The distance that the leucine β-naphthylamidase (LNAase) protrudes from the outer surface of the microvillous membrane was investigated in the rabbit small intestine, using an immunological technique combined with electron microscopy. Microvillous vesicles were incubated with various amounts of preparations of IgG against LNAase (anti L IgG) at 37 C for 60 min and then at 4 C for 20 hr or for 3 days. Vesicle agglutination was then determined by LNAase or sucrase assay methods. At the same time, inhibition of LNAase activity by anti-L IgG was measured. Microvillous vesicles with an LNAase:sucrase (L:S) ratio of 1.62 were quantitatively agglutinated by anti-L IgG during 20-hr incubation at 4 C, but vesicle agglutination did not occur in microvillous vesicles with an L:S ratio of 0.32, even after 3 days. LNAase inhibition by anti-L IgG was inhibited to a similar degree in both microvillous preparations. The extent of agglutination and inhibition attained by 15 μl of anti-L IgG per unit of LNAase after 20-hr incubation at 4 C were plotted against the L:S ratios of the vesicle preparations. About 90% or more agglutination was observed with vesicles having an L:S ratio higher than 1.4. Agglutination decreased hyperbolically when the L:S ratio was below this value. LNAase inhibition by anti-L IgG was independent of the L:S ratio and was about 65% over the range of L:S ratios examined. In contrast to anti-L IgG, IgG against sucrase-isomaltase complex (anti-SI IgG) quantitatively agglutinated vesicles with a high L:S ratio of 2.26, i.e., rich in LNAase and deficient in sucrase-isomaltase complex, as well as those with a low L:S ratio (0.32). Microvillous vesicles with an L:S ratio of 1.0 were seen ultrastructurally to be closed by the trilaminar membrane with a smooth surface. When these vesicles were incubated with anti-L IgG, continuous or bunch-like structures, appeared on the outer membrane; these protruded 16 nm from the surface. Negative staining showed a 15-nm wide particulate layer on the edge of untreated vesicles; this layer was not broadened by treatment with anti-L IgG. A comparison of these results with previous results in which vesicles were treated with anti-SI IgG has led the authors to conclude that LNAase, or at least its antigenic sites, protrudes about 10 nm from the outer surface of the microvillous membrane.

8121 DISACCHARIDASE AND LYSOSOMAL ENZYME ACTIVITIES IN AMNIOTIC FLUID, INTESTINAL MUCOSA AND MECONIUM: CORRELATION BETWEEN MORPHOLOGY AND DISACCHARIDASE ACTIVITIES IN HUMAN FETAL SMALL INTESTINE.

(Eng.) Antonowicz, I.; Milunsky, A.; Lebenthal, E.; Schwachman, H. (Harvard Medical Sch., Boston, MA). *Biol. Neonate* 32(5/6):280-289; 1977.

The relation of sucrase, maltase, and lysosomal enzyme activities to gestational age was investigated in amniotic fluid specimens obtained from 126 women between 14 and 28 weeks of pregnancy. In addition, the morphological development of intestinal mucosa was correlated with sucrase and maltase activities during gestation and the distribution of the brush border membrane-bound and lysosomal enzyme activities in amniotic fluid, intestinal mucosa, and meconium was analyzed in human fetal intestinal mucosa and meconium. Sucrase and maltase activity, which had a relatively constant level between the 14th and 18th weeks, showed a declining pattern
thereafter, reaching a very low level at the
26th week of gestation. No lactase activity
could be detected between 14 and 26 weeks of
gestation. The lysosomal enzymes, α-glucosi-
dase and β-D-fucosidase, showed patterns simi-
lar to the activities of sucrase and maltase.
No marked changes in *N*-acetyl-β-glucosaminidase
activity were noted between weeks 14 and 23. Be
tween the 11th and 20th weeks, the primitive vil
seen in sections of small intestine achieved mor
uniform shape and the crypts became deeper. The
activities of intestinal sucrase and maltase at
the 10th week were relatively low. Starting wit
12th week, these activities increased, and remai
approximately the same until the 26th week. At
term, the mucosa was completely mature, and the
villus to crypt ratio was about 6 to 1; the acti
ties of maltase and sucrase at this time reached
the values found in babies <1 yr of age. The ra
of the activities of sucrase and maltase in in-
testinal mucosa to that in amniotic fluid was re
tively constant between the 14th and 18th weeks,
being between 5 and 8 times higher in intestinal
mucosa than in amniotic fluid. After the 18th
week, disaccharidase activities decreased to a
very low value in amniotic fluid, while in the
intestinal mucosa they remained approximately at
the same level. The highest dissacharidase leve
were found in fetal meconium from two fetuses 17
and 18 weeks old. The ratio of α-glucosidase in
amniotic fluid to intestinal mucosa differed fr
that of sucrase and maltase being approximately
The distribution of β-D-fucosidase activity dif-
fered considerably from that of α-glucosidase at
17 and 18 weeks. The differences in distributi
of the disaccharidases and lysosomal α-glucosid
in amniotic fluid and intestinal mucosa suggest
that these enzymes originate in diverse fetal t
sues.

8122 EFFECT OF LACTOSE FEEDING ON CELL REN
DISACCHARIDASE ACTIVITY AND CALCIUM-B
ING PROTEIN CONTENT IN THE INTESTINAL MUCOSA OF
RATS.

(Eng.) Pansu, D.; Bellaton, C.; Bosshar
A. (Hopital Edouard Herriot, 69374 Lyon Cedex 2
France). *Ann. Biol. Anim. Biochim. Biophys.* 18
(1):127-132; 1978.

To determine how lactose increases the absorpti
and retention of calcium in the skeleton, intes
tinal mucosal structure and the levels of disac
idase activity, calcium binding protein (CaBP),
and calcium in the intestinal mucosa were studi
in male Wistar rats fed lactose (30% of diet)
from weaning. Rats were killed at the age of 4
months for enzymatic and autoradiographic studi
at 2, 3, 4, and 5 months for the CaBP assay, an
at 4 and 12 months for skeletal calcium measure
ment. Prolonged lactose feeding induced signif
icant cecal hypertrophy without mucosal hyperpl
The cecal weight increased, but mucosal weight
DNA content were similar in the lactose-fed an
control rats. Labeling and mitotic indices we
also unaltered. The specific activity of inve
tase was significantly higher in the duodenum
(36.1 ± 2.33 mU/mg protein) and cecum (0.46 ±
mU/mg) of lactose-fed rats than in control rat

3.9 and 0.23 ± 0.1 mU/mg, resp., $p<0.05$). The 3P content decreased with age in the duodenum controls; it was present in the jejunum and eum (20.40 and 5.0 nmol calcium bound/mg protein, sp.) at 2 months of age but disappeared at 3 nths. When a diet containing lactose plus vita- D (50 IU/100 g) was given, CaBP content de- eased at all levels of the intestine and disap- red from the duodenum when the rats were 5 nths old. The total body calcium content in onth-old lactose-fed rats was similar to that controls. However, the calcium content was kedly higher (1.23 mg/100 g) in 12-month-old, tose-fed rats than in controls (1.0 g/100 g). tose administration caused no changes in the ll intestine that could explain the increased orption and retention of calcium. The decrease CaBP content indicates that lactose increases orption by a mechanism that is not related to ive vitamin-dependent transfer.

GENERAL

0 MODELING THE GASTROINTESTINAL SYSTEM. (Eng.) Finkelstein, S. M.; Dreiling, A.; Blesser, W. B. (Mount Sinai Sch. Medicine, y Univ. New York, New York, NY). *Bull. N.Y. d. Med.* 54(3):251-260; 1978.

asic block diagram model was developed to de- ibe the overall operation of the gastrointes- al system and to study the interaction between various organs of the system during digestion. primary blocks of the system represent the mach, duodenum, pancreas, and gallbladder. Ex- ation signals for the system are the neural gus) responses to food intake and the volume ects of the constituents of food, particularly fat, carbohydrate, and protein. The initial study proposes that both the pH and the volume of the ingested foodstuff stimulate the primary system blocks. The model describes the acid and gastrin responses of the stomach wall, the duodenal hormonal response to the secretin concentration, and the gallbladder response to cholecystokinin in a total closed-loop configuration. Once the model has been validated and quantitative values have been assigned to the various blocks, the model can be simulated on a digital computer and then can be used to study the interactive effect of each subsystem on total system function and the sensitivity of the system's response to variations in parameters.

8131 INFLUENCE OF BODY POSITION, DRY AND WATER SWALLOWS, SMOKING, AND ALCOHOL ON ESOPHAGEAL ACID CLEARING. (Eng.) Kjellen, G.; Tibbling, L. (Univ. Hosp., Linkoping, Sweden). *Scand. J. Gastroenterol.* 13(3):283-288; 1978.

The usefulness of the acid-clearing test (ACT) was further evaluated in 21 normal subjects by investigating the effects of differing the body position, swallowing water, smoking, and drinking alcohol on the test results and reproducibility. The ACT was carried out according to a reported procedure, with some modifications. The pH-electrode, which was calibrated against buffer solutions of pH 4.0 and 7.0 before each subject was investigated, was placed 5 cm above the lower esophageal sphincter (LES). The electrode was connected to a pH-meter. Fifteen milliliters of 0.1 M HCl was instilled in the esophagus over 30 sec, with the catheter placed 15 cm above the LES. The subject swallowed dry every 30 sec, and the number of swallows to reach a pH of 5.0 were summed. There was a significant increase in the number of swallows required to reach pH 5.0 in the head down position ($p<0.003$), after smoking ($p<0.003$), and after drinking alcohol ($p<0.001$). The number of swallows required to reach pH 5.0 was significantly lower in subjects who swallowed 5 ml of water ($p<0.0005$) than in those who swallowed dry. Five hundred and twenty-five milliliters of saliva or 1,680 ml of water was used to raise the pH of a 15-ml solution of 0.1 M HCl to 5.0. If saliva production during 15 min was drawn off every 30 sec, which corresponds to the amount swallowed during the same period in a normal subject, and this amount was mixed with the 0.1 M HCl solution, no change in pH occurred. It is proposed that the outcome of the ACT reflects both the transporting capacity of the esophageal muscles and the production of saliva. The precision of this test is unsatisfactory for use in individual cases, but it seems well suited for the evaluation of esophageal acid clearing in larger samples.

DIAGNOSTIC PROCEDURES

CURRENT STATUS OF CARCINOEMBRYONIC ANTI-
GEN (CEA) AND CEA-S ASSAYS IN THE EVALU-
N OF NEOPLASMS OF THE GASTROINTESTINAL TRACT.

.) Nakamura, R. M.; Plow, E. F.; Edgington,
. (Scripps Clinic and Res. Foundation, La Jolla,
2037). *Ann. Clin. Lab. Med.* 8(1):4-10; 1978.

significance of carcinoembryonic antigen (CEA)
rmination in the diagnosis of gastrointestinal
lasms was compared with that of CEA-S (a homo-
ous isometric species of CEA) in 308 sera. In
tion, the properties of CEA and CEA-S and the
lts of several studies on CEA in the diagnosis
eoplasms are reviewed. The sedimentation ve-
ty for CEA is slightly higher than that for
S (6.8 versus 6.6). The isoelectric distri-
on of CEA is heterogeneous and extends from
than 3.0 to approximately 5.2 as compared with
homogeneous isoelectric point of approximately
for CEA-S. The amino acid composition of CEA
CEA-S is similar, except that CEA-S has a 10%
tive increase in lysine and a 5% decrease in
onine content. In the study of the 308 sera,
reshold of 5 ng/ml was used for the CEA assay,
a threshold of 14 U/ml was used for the CEA-S
y. Four percent of the 75 normal sera and
% of the sera from 44 patients with benign
onary diseases were positive for CEA, but none
positive for CEA-S. Similarly, the CEA test
positive in 9.8% of the sera from 92 patients
benign gastrointestinal disease and in 31.2%
e 48 patients with lung carcinoma, whereas
corresponding figures for the CEA-S assay were
nd 10.4%, resp. The CEA assay was positive
.7% of the 49 cases of gastrointestinal tu-
, whereas the CEA-S assay was positive in 46%.
e results suggest that the CEA-S assay results
ewer false-positive results and in more true-
tive results in gastrointestinal malignancies
does the conventional CEA assay.

ANGIOGRAPHIC DIAGNOSIS OF LEIOMYOMAS OF THE SMALL INTESTINE.

(Eng.) Han, S. Y.;
ete, J. S. (Univ. Alabama Sch. Medicine, 619 S.
St., Birmingham, AL 35233). *Am. J. Gastro-*
ol. 68(1):91-94; 1977.

ase of a 54-yr-old man with recurrent episodes
evere gastrointestinal bleeding over a 5-yr
d in whom small intestinal leiomyomas were
nstrated by visceral angiography is presented.
patient had experienced several episodes of
plained hematochezia. Endoscopy of the
hagus, stomach, and duodenum, and procto-
oidoscopy were unrevealing. Mesenteric arterio-
y demonstrated three vascular lesions in the
bowel. The largest measured 8 cm in diameter
was located in the distal ileum, and the other
were found in the proximal jejunum. The arter-
supplying these tumors were dilated and opaci-
earlier than the adjacent normal vessels.
e was also early visualization of effluent veins
appeared markedly dilated. At operation, mul-
e sessile and pedunculated tumors were found
ing from the muscular layers of the small intes-
. Most could be shelled out without resection of the small bowel. Removal of the large tumor required resection of the involved ileal segment. Histological examination of all tumors showed leiomyomas with cystic degeneration, hemorrhage, and infarct but without evidence of sarcomatous changes. The results in this patient and those reported in the literature suggest that leiomyomas of the small intestine may be detected by their peculiar characteristics on selective arteriography, and that this procedure may be useful in patients with massive hematochezia of unexplained origin.

8142 THE PERSISTENT LOOP SIGN IN NEONATAL NECROTIZING ENTEROCOLITIS: A NEW INDICATION FOR SURGICAL INTERVENTION?

(Eng.) Wexler, H. A. (2485 N.E. 202nd St., N. Miami Beach, FL 33180). *Radiology* 126(1):201-204; 1978.

Five patients who demonstrated a new radiographic sign in neonatal necrotizing enterocolitis are described. All patients demonstrated an unchanging dilated loop of small bowel, which was followed by perforation in three infants; the other two had surgical and/or autopsy corroboration of profound bowel wall necrosis. In the first child, early surgical intervention was not recommended because this was one of the first in which a "persistent loop" was recognized. Perforation occurred, and emergency laparotomy confirmed peritonitis with distal ileal and jejunal necrosis. Although the persistent loop syndrome was recognized in the second patient, her temporary clinical improvement delayed surgical intervention. By the time she was operated upon, she had advanced bowel necrosis, peritonitis, and ascites. In the third patient, it was not possible to resect all diseased bowel at laparotomy, and the unchanging bowel pattern in the first 3 postoperative days suggested that the remaining necrotic intestine was irreparably damaged. Since the clinical condition of the fourth child did not warrant an emergency laparotomy after an initial radiograph showed the persistent loop syndrome, one more radiograph was obtained; by this time, perforation had already occurred. The morbid condition of the fifth patient precluded surgical intervention at the time that the persistent loop was identified. Loculated free air in the right lower quadrant was noted on the next film. At autopsy, the perforation had closed over; however, as in the other cases, it was preceded by a persistent loop. These findings suggest that infants with a persistent loop be considered candidates for laparotomy.

8143 CHOLANGIOGRAPHIC ABNORMALITIES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE.

(Eng.) Rohrmann, C. A., Jr.; Ansel, H. J.; Freeny, P. C.; Silverstein, F. E.; Protell, R. L.; Fenster, L. F.; *et al.* (Univ. Washington Sch. Medicine, Seattle, WA). *Radiology* 127(3):635-641; 1978.

An analysis of cholangiographic abnormalities present in 20 patients with inflammatory bowel disease (IBD) who underwent endoscopic retrograde cholangiography is presented. In all patients, abnormal liver function tests suggested major duct obstruction. The extent of involvement of both intra- and extrahepatic systems, branching characteristics, and caliber abnormalities manifested by mural irregularities, nodules, diverticula, stenoses, ectasias, and ductal obstructions or obliterations were evaluated by cholangiography. Intrahepatic system abnormalities were found in all patients. They included diminished arborization or pruning in 16 patients, stenosis and ectasia in 15 patients, and severe obliterative changes with duct obstruction in 4 patients. Extrahepatic duct abnormalities observed in 15 patients included mural irregularity, marked in some cases, diverticula, and stenoses. The cystic duct or cystic duct remnant was abnormal in six of eight patients who had previously undergone cholecystectomy. An extrahepatic ductal abnormality apparently found exclusively in IBD patients was a saccular outpouching of the lumen producing a diverticular appearance. The characteristic cholangiographic abnormalities demonstrated make differential diagnosis of biliary tract diseases possible. Endoscopic retrograde cholangiography is recommended to exclude extrahepatic obstruction, to establish a nonoperative diagnosis, and to assist in determining the method of treatment.

8144 STUDIES ON ALKALINE PHOSPHATASE ISOENZYMES IN HEPATIC DISEASES, RELATION TO γ-GLUTAMYLTRANSFERASE.

(Eng.) Burlina, A.; Bugiardini, R. (Centro Ospedaliero Borgo Trento, 37100 Verona, Italy). *Clin. Chim. Acta* 85(1):49-54; 1978.

Activities of the isoenzymes of alkaline phosphatase (ALP) and of total γ-glutamyltransferase (γGT) were determined in the sera of 164 patients with hepatic diseases. Total ALP activity was increased over that in 40 normal controls in 45% of the patients with acute viral hepatitis, in 42% of the patients with chronic active hepatitis, in 47% of those with liver cirrhosis, and in all patients with biliary obstruction. Of the 86 patients with increased total ALP levels, 37% showed a wider ALP_2 band (the fraction migrating with α_2-globulin), 44% showed an ALP_1 band (biliary band), and 18% showed the ALP_4 band (cirrhotic band). The ALP_1 band was present in all cases of biliary obstruction, in 9% of cases of acute viral hepatitis, in 8% of chronic hepatitis cases, and in 14% of cases of cirrhosis. In the patients with a wider ALP_2 band, the γGT levels were increased but always lower than 200 U/l. In the patients with the ALP_1 band, the γGT values were all high, and 64% of the patients had a level higher than 200 U/l. In the patients with an ALP_4 band, the values were all lower than 200 U/l. There was a significant correlation between the presence of the ALP_1 fraction and increased γGT values ($r=0.733$). It appears that alkaline phosphatase fractionation gives diagnostic information not obtainable from the determination of total ALP and γGT levels.

8145 PERCUTANEOUS BIOPSY OF THE LIVER AS A PROCEDURE FOR OUTPATIENTS.

(Eng.) Knauer, C. M. (Santa Clara Valley Medical Center, 751 S
Bascom Ave., San Jose, CA 95128). *Gastroentero*
74(1):101-102; 1978.

Experience with percutaneous liver biopsy as a
outpatient procedure in 107 patients during an
18-month period is presented. The Klatskin ne
with the suction technique of Menghini is used,
usually via the intercostal approach. The outpatient is allowed to leave 6 hr after the bio
and is instructed to avoid athletic activity a
heavy lifting for the next 24 hr. The outpati
ranged in age from 8 to 73 yr. Only one patie
had a complication; he bled from the biopsy si
within 1 hr of the procedure, requiring hospit
zation for blood transfusion and surgical cont
of the bleeding site. The minimal cost saved
patient was $153.00. Liver biopsy in outpatie
is both safe and economical.

8146 DIAGNOSIS OF HEPATOBILIARY DISEASE B
^{99m}Tc-HIDA CHOLESCINTIGRAPHY.

(Eng.
Rosenthall, L.; Shaffer, E. A.; Lisbona, R.; P
P. (Montreal General Hosp., 1650 Cedar Ave., M
treal, Quebec H3G 1A4, Canada). *Radiology* 126
467-474; 1978.

The use of ^{99m}technetium-labeled N-substituted
iminodiacetic acid derivative (Tc-HIDA) cholescintigraphy for the diagnosis of hepatobilia
disease was evaluated in 18 patients with acu
or chronic cholecystitis, 17 patients with hep
cellular disease, 16 patients with biliary tr
obstruction, and 19 controls with no evidence
hepatobiliary disease. In controls, images o
biliary ducts and gallbladder were obtained w
30 min after an i.v. injection of Tc-HIDA, wh
excretion from the intestinal tract was obser
less than 60 min after injection. None of the
tients with acute or chronic cholecystitis an
cystic duct obstruction demonstrated gallblad
filling. In chronic cholecystitis with a pat
cystic duct, the gallbladder was not visualiz
with Tc-HIDA scanning in 7 of 12 cases. This
ure was rectified in one patient by administe
cholecystokinin (CCK) followed by a second do
of Tc-HIDA. In seven patients who had surgic
bypass procedures, obstruction as the cause o
juandice was excluded because of gut activity
in 60 min, no unusual dilatation of the bilia
ducts beyond what is normally observed postop
tively, and a lack of prolonged retention of
activity in the biliary system. All five pat
with serum bilirubin levels exceeding 16 mg%
were studied on consecutive days with Tc-HIDA
then ^{131}I-labeled rose bengal showed higher l
to-background ratios with the latter agent; h
ever, no gut excretion was appreciated with e
radiopharmaceutical. Accurate visualization
the ductal system was possible with Tc-HIDA i
of 12 patients with hepatocellular disease in
the serum bilirubin was between 0.8 and 4.6 m
No ductal visualization occurred with serum b
rubin levels above 5 mg%. In eight patients
partial extrahepatic obstruction and hyperbil
rubinemia up to 5 mg%, a dilated biliary tree
detected by increased radioactivity, the dia

of the ducts, and delayed washout of the test agent into the duodenum. In summary, Tc-HIDA cholescintigraphy can identify patients with acute and chronic cholecystitis and all patients with a patent cystic duct following CCK administration. The value of Tc-HIDA over standard radiography in jaundiced patients is demonstrated by its simplicity in making a definitive differential diagnosis possible when the serum bilirubin levels are 5 mg% or less.

GASTROINTESTINAL DISEASES

ESOPHAGUS

8178 RECURRENT BRONCHOPNEUMOPATHIES CAUSED BY GASTROESOPHAGEAL REFLUX IN THE CHILD. CLINICAL, RADIOLOGICAL, AND HISTOLOGICAL STUDY OF 36 CASES. (Fre.) Dutau, G.; Familiades, J.; Rochiccioli, P. (C.H.U. Rangueil, 31054 Toulouse Cedex, France). *Poumon Coeur* 33(6):351-359; 1977.

In the period January 1973-March 1977, 36 children (ages 3 months-15 yr) who had recurrent bronchitis associated with gastroesophageal reflux (GF) were studied. The bronchitis had to have occurred at least three times in 3 months, and it was often associated with a chronic cough. X-ray studies were performed with the patients in the orthostatic, procubitus, and decubitus dorsal position with Trendelenburg. Respiratory endoscopy was performed in 5 patients and esophageal endoscopy in 14. The x-ray studies did not show any pulmonary abnormalities in 22% of the children; uni- or bilateral paracardiac opacities were observed in 36%, diffuse opacities with tendency for retraction of the right upper lobe in 8%, parenchymal distention in 22%, obstructive emphysema in 5%, and bronchial inundation in 8%. Pulmonary lesions were observed in all five of the children who were examined endoscopically. The lesions observed were either localized with atelectasis, obstructive emphysema, or bronchiectasis or generalized with granulomatous reactions around food particles. The GF problems were caused by neonatal vomiting in 34%, actual vomiting in 56%, postural vomiting in 28%, and nocturnal respiratory distress associated with vomiting in 16%. It is concluded that older children often have respiratory signs of GF before gastrointestinal signs, and GF may be present for several months or years before diagnosis.

8179 SCLEROTHERAPY OF BLEEDING OESOPHAGEAL VARICES BY MEANS OF ENDOSCOPY. (Eng.) Paquet, K. J.; Oberhammer, E. (Dept. Surgery, Univ. Bonn, D-5300 Bonn-Venusberg, W. Germany). *Endoscopy* 10(1):7-12; 1978.

The treatment of hemorrhage from gastroesophageal varices by endoscopic sclerotherapy of the esophageal wall is reported in 640 patients treated over a period of 8 yr. Using a special rigid esophagoscope, which included an optical system, an aspirator, and a needle and syringe, a maximum of 1 ml of 1% Aethoxysclerol (total fluid volume not more than 50 ml) was injected into the esophageal epithelium adjacent to the varices (if sclerosing agents are partly or totally injected into the esophageal varices, hemorrhage from varices of the stomach will occur). After two to four injections adjacent to the varices during 1 week, the remission of the varices was documented endoscopically or radiographically. Patients required reevaluation at 4-6 month intervals. After two to three sessions of sclerotherapy, the interval of control could be extended up to 1 yr without new danger of hemorrhage. If hemorrhage recurred or if increasing size of the varicosities was observed, sclerotherapy was repeated. If liver function improved, a portasystemic shunt was performed. In 211 patients, the indication for sclerotherapy was uncontrollable hemorrhage; in 386 patients it was performed in the bleeding-free interval for either decompensated liver function, hepatic precoma, the absence of anastomosable portal vessels, or thrombosed shunts. The remaining 43 patients were treated because of impending hemorrhage and portal hypertension. The overall mortality rate was 14.5%, the main causes of death being liver coma (42/93 patients), uncontrollable hemorrhage (26/93), and mediastinitis and pyothorax (8/93). About 50% of the patients survived for periods of 1-8 yr. Most of the 65% still alive have experienced no further bleeding. It is concluded that sclerotherapy is the method of choice in the treatment of massive hemorrhage from esophageal varices. It is indicated in patients with decompensated liver function and whenever a shunt procedure is impossible or inadvisable.

8180 ULCERATIVE ESOPHAGITIS AND COLITIS IN A PEDIATRIC PATIENT WITH BEHCET'S SYNDROME: RESPONSE TO STEROID THERAPY. (Eng.) Lebwohl, O.; Forde, K. A.; Berdon, W. E.; Morrison, S.; Challop, R. (Columbia Univ. Coll. Physicians and Surgeons, 630 W. 168th St., New York, NY 10032). *Am. J. Gastroenterol.* 68(6):550-555; 1977.

The case of a patient with Behcet's syndrome who developed radiologic and endoscopic evidence of ulcerative esophagitis and colitis is presented. The patient had been noted since infancy to have recurrent painless oral ulcers. At 11 yr of age, she developed painful genital and perianal ulcers, and oral ulcers recurred. Her symptoms resolved with treatment, which included prednisolone. Six months later, she presented with diffuse abdominal pain and persistent oral ulcers. Stool guaiac tests were positive, but sigmoidoscopy and barium enema examinations were normal. The symptoms resolved, and the patient did well on varying doses of prednisone for over 2 yr. At this time, she developed frontal headaches, episodes of nausea and vomiting, photophobia, diplopia, and oral ulcers, all attributed to Behcet's syndrome with central nervous system involvement. The symptoms gradually resolved while she continued to take 10 mg of prednisone every other day. One year later, she developed epigastric pain, and an upper gastrointestinal series revealed a large posterolateral ulcer in the lower esophagus, felt to be an impending perforation. Stool hematest was intermittently positive, and a barium enema examination showed polypoid filling defects in the cecum and ascending colon. The patient's symptoms gradually improved after the prednisone dose was increased to 60 mg per day. A repeat esophagram demonstrated partial healing of the esophageal ulcer. Her abdominal symptoms recurred after tapering the steroid dose. Fiberoptic colonoscopy revealed a localized area of severe inflammatory bowel disease characterized by ulceration, shaggy fibrinous exudate, friable mucosa, mucosal pseudopolyps, and some narrowing of the lumen, all in the cecum and proximal colon. The patient's symptoms resolved after the steroid dose was again increased to 60 mg daily, and a repeat barium enema showed considerable improvement in the appearance of the cecum and ascending colon. Colitis and esophageal ulceration should be considered in patients with Behcet's syndrome who present with gastrointestinal symptoms.

8181 THE RADIOLOGICAL DIAGNOSIS OF PEPTIC ULCER OF THE ESOPHAGUS. (Ger.) Truber, E.; Treichel, J. (Klinikum Steglitz der Freien Universitat, Hindenburgdamm 30, 1000 Berlin A5, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 128(2):111-115; 1978.

Peptic esophageal ulcer was diagnosed radiologically in 14 patients. The radiological examination also demonstrated esophagogastric reflux in all 14, esophagitis in 10, axial hiatal hernia in 13, and stenosis in 2. The ulcer was located at the esophagogastric junction in 13 cases and 5 cm above the cardia in the other. Endoscopy confirmed the x-ray diagnosis in all 11 cases examined. Hypotonic esophagography is believed essential for the differentiation between benign and malignant ulcers.

STOMACH

8198 GASTRIC LESION AND PERNICIOUS ANEMIA: A FAMILY STUDY. (Eng.) Varis, K.; Stenman, U. H.; Lehtola, J.; Siurala, M. (Second Dept. Medicine, Univ. Helsinki, Helsinki, Finland). *Acta Hepatogastroenterol.* 25(1):62-67; 1978.

To investigate the genetic contribution in the deficient secretion of intrinsic factor (IF) that underlies pernicious anemia, 5 subjects with pernicious anemia, 17 of their first-degree relatives, 3 subjects with atrophic gastritis, and 9 of their first-degree relatives were studied gastroscopically, bioptically, functionally, and immunologically. The results showed similarities of morphology, function, and immunology of the stomach within each family studied. Relatives of subjects with pernicious anemia accumulated features generally seen in overt pernicious anemia: slight to severe atrophic gastritis with normal or slightly altered antral mucosa, achlorhydria, low secretion of IF, and high levels of serum gastrin and parietal call antibody. Two relatives actually had overt pernicious anemia as judged by IF secretion. It was possible to identify a subgroup of relatives with overt pernicious anemia or a high risk of pernicious anemia on the basis of elevated serum gastrin levels, achlorhydria, and low IF secretion. IF secretion below 500 U/hr was seen exclusively in association with IF antibodies in the gastric juice and advanced atrophy of the gastric body mucosa (except in one subject with a resection stomach); four of these nine subjects had overt pernicious anemia on the basis of decreased serum vitamin B_{12} levels. The family of a subject with atrophic gastritis showed high levels of parietal cell antibodies.

8199 EFFECT OF PROLONGED ADMINISTRATION OF ANTI-INFLAMMATORY AND ANALGESIC DRUGS ON GASTRIC MUCOSA. (Fre.) Pascal, J. P.; Tournut, J. J. (CHU Toulouse-Purpan, F 31052 Toulouse Cedex, France). *Gastroenterol. Clin. Biol.* 2(1):15-22; 1978.

A histological study of the gastric mucosa was undertaken in 43 patients who had been on anti-inflammatory and/or analgesic drugs for 1-30 yr because of various arthritis types (mainly rheumatoid arthritis). Principally, the drugs involved were ketoprofene, indomethacin, acetylsalycilic acid, corticoids, buprofen, and sodium diclofenate. A group of 25 patients hospitalized in the gastroenterological unit for functional disorders were studied for comparison. Esophagogastroduodenal endoscopy was performed on each patient, and 10 biopsies of the mucosa were taken along the gastric curvature. A repeat of the study was performed on 12 of the arthritis patients 5-8 months after interruption or decrease in dosage of their analgesic or anti-inflammatory medication. A single pathologist rated all the biopsies as superficial gastritis, superficial gastritis with atrophy, atrophy, intestinal metaplasia, or normal. Specimens rated as atrophic were three times more frequent in the group of patients on the anti-arthritic drugs. Distribution of gastric lesions was not different in the two groups of patients. Reexamination of the 12 patients who had stopped or decreased their medication showed a significant ($p<0.001$) decrease in the number of specimens rated as atrophic; the frequency of metaplasia had not changed in these patients. It is concluded that the drugs used by these patients cause atrophy of the gastric mucosa but not superficial gastritis or intestinal metaplasia.

8200 ^{67}Ga-CITRATE SCANNING IN GASTROINTESTINAL MALIGNANCIES. (Eng.) Douds, H. N.; Berens, S. V.; Long, R. F.; Caplan, G. E. (Memorial Medical Center, P.O. Box 23089, Savannah, GA 31403). *Clin. Nucl. Med.* 3(5):179-183; 1978.

The use of ^{67}Ga-citrate scanning in cases of gastrointestinal (GI) malignancy is reported in seven patients and surveyed in the literature to point out specific situations where gallium scanning may be diagnostic. Seven proven cases of GI malignancy in which initial ^{67}Ga scans were positive were collected. Cases 1 and 2 were adenocarcinomas of the stomach, case 3 was a mixed-cell histiocytic lymphoma involving the stomach and cervical nodes, case 4 was a gastric lymphoma, case 5 was a recurrent small bowel lymphoma at the ligament of Treitz, case 6 was a recurrent cecal adenocarcinoma, and case 7 was a recurrent rectal histiocytic lymphoma. GI x-ray studies were normal in cases 4, 5, and 6 and inconclusive in cases 1 and 2. In case 3, a positive GI series, showing thickening of gastric folds suspicious for lymphoma, was supported by the ^{67}Ga scan, with abnormal gastric uptake from the fundus to the mid-antrum. In the normal or inconclusive GI series, increased gallium uptake during the ^{67}Ga scan indicated the location of the malignancy. In case 7, the recurrent rectal lymphoma was confirmed with the scan, which further revealed the presence of extensive upper abdominal disease. The literature is generally pessimistic regarding the value of gallium scanning in suspected GI malignancies, the major objection being its obscuring activity in bowel content. The authors emphasize that meticulous bowel cleansing prior to scanning and repeat scans at 72 and 96 hr improve the diagnostic yield and make it possible to visualize the abnormal uptake within the bowel itself. Increased use of ^{67}Ga scanning is recommended as a simple, noninvasive study that has been particularly useful in support of radiographic contrast studies of suspected carcinomas, in detecting the recurrence of known malignancy, in defining the extent of primary and metastatic disease, and as a diagnostic tool for debilitated patients.

8201 RELATIONSHIP BETWEEN DIET AND CARCINOMA OF THE STOMACH, COLON, RECTUM, AND PANCREAS IN FRANCE. (Fre.) Meyer, F. (Hopital E.-Herriot, Pavillon H, F 69374 Lyon Cedex 2, France). *Gastroenterol. Clin. Biol.* 1(12):971-982; 1977.

Age-standardized mortality rates for the years 1968 and 1969 for cancer of the stomach, colon, rectum, and pancreas were compared with the average consumption of bread, potatoes, fresh vegetables, fresh fruits, beef, eggs, fish, cheese, butter, oil, sugar, wine, and beer in eight districts of France. Consumption of foods that supply the same nutrients (butter/oil, wine/beer) showed significant ($p \leq 0.05$) negative correlations as did consumption of the pairs potatoes/fruits, butter/fruits, and butter/wine. There was a significant ($p \leq 0.05$) positive correlation in the consumption of bread/sugar/eggs, of oil/wine/vegetables, and of potatoes/beer (except in the North), fruits/oil, and fruits/vegetables. Beef consumption was not significantly correlated with the mortality rates for any of the cancers; moreover, the correlation was negative in sign for stomach cancer mortality ($r=0.58$) and colon cancer mortality ($r=0.33$). Because the food consumption patterns and cancer mortality patterns of the North and the Mediterranean regions are atypical of those in the other six regions, the sign, absolute value, and level of significance of the correlations varied considerably when first one and then both of these regions were excluded from the analysis. The significant ($p \leq 0.05$) correlations for all eight regions were between stomach cancer mortality and fruit ($r=-0.66$) and oil ($r=-0.72$) consumption; colon cancer mortality and potato ($r=0.68$), fruit ($r=-0.83$), butter ($r=0.74$), and oil ($r=0.83$) consumption; rectal cancer mortality and potato ($r=0.82$), fruit ($r=-0.77$), oil ($r=-0.71$), and beer ($r=0.73$) consumption; and pancreatic cancer mortality and potato ($r=0.67$), wine ($r=0.69$), and beer ($r=0.73$) consumption. When the North was excluded from the analysis, the most important differences in the correlations were that potato consumption lost its positive significance in colon, rectal, and pancreatic cancer mortality due to large decreases in the absolute value of r, butter consumption reached significance ($p \leq 0.05$) in correlation with stomach cancer ($r=0.87$), wine consumption lost its negative significance in correlation with pancreatic cancer, and beer consumption decreased below positive significance in correlation with rectal and pancreatic cancer. When the Mediterranean region was also excluded from the analysis, the most important changes were that potato consumption was again significant ($p \leq 0.05$) in stomach cancer mortality ($r=0.86$), the fruit consumption correlation changed markedly in either absolute value or sign and became insignificant in relation to colon and rectal cancer mortality, butter consumption became significant ($p \leq 0.05$) in rectal cancer mortality ($r=0.90$), and oil consumption los its negative significance in colon cancer mortalit No testable hypothesis can yet be made from these data.

8202 BASIC EXPERIMENTS ON ORAL ADMINISTRATION OF 5-FLUOROURACIL EMULSION AS ADJUVANT CHEMOTHERAPY TO SURGICAL TREATMENT FOR GASTRIC CANCER. (Eng.) Watanabe, S.; Nakao, E.; Cho, K.; Nishioka, B.; Fujita, Y.; Takahashi, T.; *et al.* (Kyoto Prefectural Univ. Sch. Medicine, Kyoto, Japan). *Jpn. J. Surg.* 8(1):41-50; 1978.

The absorption and distribution of 5-fluorouracil (5-FU) into the blood and tissues of Donryu rats was investigated to evaluate the usefulness of 5-F as adjuvant chemotherapy. An emulsion or solution of 5-FU (100 mg/kg body weight) was administered p.o. to the rats, and the 5-FU level was measured in the blood, kidneys, liver, stomach, duodenum, a lymph nodes at intervals of 30 min, 1, 2, 4, 6, 8, 12, and 24 hr. To investigate the absorption of 5-FU in the stomach in detail, the experiments wer also performed on pylorus-ligated rats. The highest levels of 5-FU were found in the stomach and duodenum; the maximum concentration achieved by use of the emulsion was 1.5 times that after use of the solution. An appreciable concentration of 5-FU was maintained over a longer period of time by the emulsion. High levels of 5-FU were also detected in the lymph and lymph nodes. In the lymph the maximum concentration attained by the 5-FU emulsion was three times higher than the maximum c centration attained by the 5-FU solution, and in the lymph nodes, the emulsion maximum concentration was twice as high as the solution maximum. The higher concentration was maintained over the course of the experiment. In pylorus-ligated rats the 5-FU concentration in the mucosa of the stomach was 77.3 ± 38.7 μg/g following the 5-FU emulsi and 34.1 ± 17.3 μg/g following the solution. In the lymph nodes, the 5-FU concentration was 0.9 ± 0.31 μg/g for the emulsion and 0.4 ± 0.13 μg/g for the solution. The studies show that 5-FU can be absorbed directly from the mucous membrane of the stomach even when administered as an emulsion. An appreciable amount of 5-FU is transported to the lymph nodes by way of the lymphatic capillaries. The findings, in general, may be explained by the enhancement of drug adsorbility, permeability, and retentivity in the tissues of the gastrointestinal tract when it is administered in the form of an emulsion. It is concluded that the p.o. administration of 5-FU emulsion is an effective adjuvant to surgery for gastric cancer, particularly for lymph node metastasis.

8203 TRANSPYLORIC EXTENSION OF GASTRIC CARCINOMA. (Eng.) Menuck, L. (Palomar Hosp., Escondido, CA 92025). *Am. J. Dig. Dis.* 23(3): 269-274; 1978.

The barium studies of the upper gastrointestinal tract in 88 patients with gastric carcinoma were evaluated to document the frequency of gross pyloric extension and to correlate the radiographic appearance with the gross anatomical changes in the pylorus and duodenal bulb. Of the 88 cases of gastric carcinoma, 17 showed transpyloric extension of the tumor; the phenomenon was microscopic in 10 cases and gross in 7. In all of the latter seven patients, the roentgen examination showed a malignant lesion of the antrum and/or pylorus with an associated abnormality of the duodenal bulb. The duodenal abnormalities included a mass lesion, mucosal destruction, or bizarre thickened folds. In six of the seven cases, the transpyloric extension was appreciated preoperatively. Three of the seven cases were properly diagnosed radiographically. Three cases were incorrectly diagnosed as gastric lymphoma because the examiner considered the finding of transpyloric extension to favor lymphoma, even though the antral abnormality was more consistent with carcinoma. The seventh case was initially believed to represent chronic peptic ulcer disease with antral and duodenal changes; the patient initially refused endoscopy, but the lesion was correctly diagnosed at 6-month follow-up. Only 3/88 cases showed pyloric obstruction. The present study fails to support the frequent assumption that since gastric carcinoma arises from the mucosa, it will encroach on the pylorus and obstruct it before transpyloric extension takes place.

8204 THE NATURAL HISTORY OF THE DOUBLE PYLORUS. (Eng.) Hegedus, V.; Poulsen, P. E.; Reichardt, J. (Glostrup Univ. Hosp., Copenhagen, DK-2600 Glostrup, Denmark). *Radiology* 126(1):29-34; 1978.

The natural history of the development of a double pylorus was investigated by examining the subjective complaints, clinical and radiological findings, and endoscopic observations in 11 patients with prepyloric ulcers and a fistula. Seven patients had undergone upper gastrointestinal series prior to the discovery of a fistula, and the prepyloric ulcers in these patients were located on the lesser curvature in four cases and the major curvature in two. Symptoms prior to the discovery of the antroduodenal fistula included abdominal pain, postprandial pain, vomiting, and gastrointestinal bleeding. In seven cases, significant relief of discomfort was obtained simultaneously with the establishment of the gastroduodenal fistula, and all these patients became asymptomatic. The remaining four patients were of doubtful clinical significance. One of these patients experienced recurrence of symptoms despite surgery. The consequences of the development of the fistula were difficult to evaluate in the other three patients because medical treatment was given at the time the double pylorus was discovered. Six case reports of patients in whom symptoms resolved after the development of the fistula are presented. One of these was particularly interesting, as the ulcer on the greater curvature did not affect the pancreas but penetrated into the duodenum. These cases demonstrate that the double pylorus is the result of ulcer penetration and that this fistula can be a sign of spontaneous recovery from ulcerative disease.

8205 DYNAMIC SCINTIPHOTOGRAPHIC STUDY OF THE ANTRAL MUCOSA WITH ^{99m}Tc-PERTECHNETATE IN HYPERGASTRINEMIA CAUSED BY RETAINED ANTRUM. (Ita.) Sciarretta, G.; Cavicchi, L.; Turba, E.; Fini, A.; Malaguti, P.; Cacciari, C. (Ospedali di Bologna, Bologna, Italy). *Bull. Sci. Med.* 149(2): 85-90; 1977.

The diagnosis of retained antrum by gastrin level test results and scintiphotographic studies is reported with reference to two male patients. Both patients had undergone Billroth II gastric resections for duodenal ulcers 6 and 9 months previously. The suspected diagnosis of retained antrum was based upon the elevated basal levels of serum gastrin in both of these patients (140 and 100 pg/ml compared with a normal value 60 ± 15 pg/ml). The tests of gastrin response (using secretin, calcium, and a protein meal) excluded the diagnosis of gastrinoma and supported the suspicion of retained antrum. In one of the patients, an endoscopic biopsy of the duodenal stump demonstrated the presence of antral mucosa. The scintiphotographic study with ^{99m}Tc-pertechnetate clearly demonstrated the presence of an area of activity on the bottom of the duodenal stump in both patients. The patients underwent resection of the retained antrum; histological examination of the tissue confirmed the diagnosis and follow-up studies revealed that the basal gastrinemia markedly decreased (to 75 pg/ml and 55 pg/ml resp.). The use of scintiphotography in cases of suspected retained antrum is advocated by the authors because it is a simple technique that gives a clear, differential diagnosis in these patients.

8206 A PROSPECTIVE COMPARATIVE STUDY OF CLINICAL AND HISTOLOGICAL CHARACTERISTICS IN ICELANDIC AND DANISH PATIENTS WITH GASTRIC ULCER, DUODENAL ULCER, AND X-RAY NEGATIVE DYSPEPSIA: I. STOMACH

Peptic Ulcers

257 IN-PATIENT TREATMENT OF PEPTIC ULCER WITH CIMETIDINE. I. EFFECT ON DUODENAL ULCER ALING.

(Ger.) Malchow, H.; Sewing, K. F.; Al-nus, M.; Horn, B.; Schomerus, H.; Dolle, W. (Medi-nische Universitatsklinik, Otfried-Muller-Strasse , 7400 Tubingen, W. Germany). *Dtsch. Med. Wochen-hr.* 103(4):149-152; 1978.

e effectiveness of cimetidine in the treatment peptic duodenal ulcer was studied in 67 patients a 6-week double-blind trial. All patients re-ived dimagnesium aluminum trisilicate (3 g/day). irty-three patients received cimetidine (4 x 300 ;/day p.o.) and 34 controls received placebo. Pain lief was significantly (p<0.01) better during the t week of treatment in the cimetidine-treated oup than in the controls. Healing of the ulcers s observed in 16/33 patients in the cimetidine oup and in 7/34 patients in the placebo group ter the first 2 weeks of treatment, but there was statistically significant difference at the end the third week (23/33 versus 18/34, resp.), nor the end of the 6-week treatment (30/33 versus /34, resp.). Neither basal nor pentagastrin-imulated acid and pepsin secretions were af-cted by the 17-day administration of cimetidine. e drug had to be withdrawn in two cases because elevated serum creatinine levels, but there re no other side-effects. Cimetidine had no ng-term effects independent of the period its presence in the blood. Compared with lit-ature data on out-patients, the in-patient treat-nt caused faster healing in both the cimetidine d placebo groups.

58 IN-PATIENT TREATMENT OF PEPTIC ULCER WITH CIMETIDINE. II. CONTROLLED DOUBLE-IND TRIAL IN GASTRIC ULCER PATIENTS.

(Ger.) wing, K. F.; Malchow, H.; Albinus, M.; Horn, B.; homerus, H.; Dolle, W. (Pharmakologisches In-itut der Universitat, Wilhelmstrasse 56, 7400 bingen, W. Germany). *Dtsch. Med. Wochenschr.* 3(4):152-154; 1978.

e effectiveness of cimetidine (4 x 300 mg/day o.) on the healing of peptic gastric ulcer was udied in 20 patients and in 16 placebo-treated ntrols in a double-blind trial. All patients ceived dimagnesium aluminum trisilicate (3 g/ y). The average duration of the in-patient eatment was 28 days, and follow-up for healing ntinued for up to 6 weeks. The number of pa-ents healed at the end of the 3rd week was 10/20 the treated group versus 5/16 in the control oup. At the end of the 6th week, the ulcers were aled in 17/20 patients versus in 10/16 placebo-eated controls; the difference was not statisti-lly significant. There were also no signif-ant differences in pain alleviation. Cimetidine d no influence on pentagastrin-stimulated acid d pepsin secretion. There were no serious un-ward reactions to cimetidine.

8259 MAXIMUM ACID OUTPUT IN DUODENAL ULCER PATIENTS WITH DIFFERENT LENGTH OF HISTORY AND CONTROLS WITHOUT DYSPEPSIA.

(Eng.) Kronberg, O.; Christiansen, P. M. (Bispebjerg & Hvidovre Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12 (8):957-962; 1977.

To investigate the hypothesis that maximum acid output (MAO) in duodenal ulcer (DU) patients is normal in those with an ulcer history of <3 yr but elevated in those with a longer history, MAO was measured in 3 groups of 21 men and 4 groups of 9 women with operatively verified DU and ulcer histories of <3, 3-6, or 7-10 yr. The results were compared with that of age-matched controls with no history of dyspepsia. An augmented histamine test was performed on patients and controls. The activity of the ulcer at surgery was evaluated as to the presence of an ulcer crater or duodenal scar. The rate of recurrent DU was studied in relation to the length of ulcer history. No significant relationship was found between the length of ulcer history and the activity of the ulcer or the recurrence rate. The risk of recurrent DU showed no tendency to increase with the length of history before vagotomy. For both men and women, the uncorrected mean values of MAO were significantly higher in patients with symptoms for <3 yr compared to controls (men, 42.1 ± 3.4 versus 24.2 ± 0.8 or 20.8 ± 1.6 mmol/hr in controls, p<0.001; women, 24.9 ± 2.9 versus 16.4 ± 1.5 mmol/hr in controls, p<0.05), but patients with longer histories had MAO values similar to those of the patients with <3 yr histories. When MAO values were corrected for weight or stature, they were significantly higher (p<0.001) than control values in all men (regardless of the length of ulcer history). Neither the men nor women showed any significant changes of MAO with increasing length of history. In a group of 11 men with duodenal ulcer histories of less than 1 yr, the MAO values (uncorrected and corrected) were also significantly higher (p<0.001) compared with controls. When groups of 16 men with histories of up to 22 yr were studied, a fixed proportion of hypersecretors (uncorrected MAO above 30 mmol/hr) was found among patients with up to an 18-yr ulcer history; when history exceeded 18 yr, a tendency toward smaller numbers of hypersecretors was noted. The present study does not support the hypothesis that the risk of ulcer recurrence after vagotomy and drainage is related to MAO before surgery, nor does it support the assumption that gastric hypersecretion is a result of duodenal ulceration. MAO was elevated above normal values in all ulcer patients, even those with histories of less than 1 or 3 yr.

8260 QUANTITATIVE STUDIES OF GASTRIN CELLS (G CELLS) AND PARIETAL CELLS IN RELATION TO GASTRIC ACID SECRETION IN PATIENTS WITH PEPTIC ULCER DISEASE.

(Eng.) Stave, R.; Myren, J.; Brandtzaeg, P.; Gjone, E. (Rikshospitalet, Oslo, Norway). *Scand. J. Gastroenterol.* 13(3):293-298; 1978.

Stomach specimens from 42 patients subjected to partial gastric resection for gastric ulcer (12), duodenal ulcer and uremia (14), duodenal ulcer without uremia (11), and gastric cancer (5) were studied to determine possible relationships between acid output, parietal cell density in the body mucosa and the various parameters of the antral G cell population. Gastric acid secretion was measured before surgery. In the material as a whole, the antral G cell density was 35.6 ± 15.2, the G cell distribution was 71.7 ± 21.5 cm^2, the total antral G cell mass was 2,551 ± 1,780.3, and the parietal cell density in the body mucosa was 190.0 ± 89.4. The basal acid output (BAO) was 3.7 ± 4.3 mEq/hr and the pentagastrin-stimulated acid output (MAO) was 25.8 ± 15.7 mEq/hr. In the material as a whole there was a significant positive correlation between the parietal cell density and MAO ($r=0.589$, $p<0.01$), negative correlation between parietal cell density and age ($r=-0.365$, $p<0.02$), and positive correlation between antral G-cell mass and BAO ($r=0.331$, $p<0.05$). Analysis of the individual groups revealed significant correlations between parietal cell density and MAO in patients with duodenal ulcer and uremia ($r=0.711$, $p<0.05$) and in those with gastric cancer ($r=0.934$, $p<0.05$) and a borderline significance in the gastric ulcer patients ($r=0.520$). There was a significant negative correlation between parietal cell density and age in the group of patients with duodenal ulcer and uremia ($r=-0.606$, $p<0.05$). The correlation between G cell mass and BAO was at the borderline of significance in the gastric ulcer patients ($r=0.539$) and in the duodenal ulcer with uremia group ($r=0.537$). No correlation between the parietal cell density and the various parameters of the antral G cell population in the material as a whole or in any of the individual patient groups was found. There was a falling trend in gastric acid output with advancing age. Possible flaws in the experimental design, including the heterogeneity of the patient material as a whole, the limited categorization, the limited numbers of patients, and the inability to match patients with regard to age and sex are analyzed. The authors conclude that, as each of five hormones has the dual proper-smaller LA and LA:PY ratio increments; this did not occur with X. B usually increased LA and the LA:PY ratio. In the treatment of cirrhotic patients, a combination of G and insulin is recommended. If G cannot be used, then X or S is preferred to F. The simultaneous administration of sugars and insulin seems advantageous, while the combination of sugars with B appears risky.

8261 GASTRIC EMPTYING OF INGESTED ACID AND ITS EFFECTS ON PLASMA GASTRIN AND SECRETIN IN DUODENAL ULCER SUBJECTS. (Eng.) McLoughlin, J. C.; Green, W. E. R.; Buchanan, K. D. (Dept. Medicine and Surgery, Queen's Univ. Belfast, Belfast, Northern Ireland). *Scand. J. Gastroenterol.* 13(3): 313-319; 1978.

The gastric emptying of 250 ml of 0.1 M hydrochloric acid labeled with 1 mCi ^{113m}Indium chloride was followed in 16 normal and 15 duodenal ulcer (DU) subjects to evaluate their ability to handle a standard acid load. The time required for dischar
of half of the load was significantly shorter in D
subjects than in controls (33.6 ± 2.7 versus 48.5
5.3 min, $p<0.025$). The times required for the los
of the initial 20% of the load and for the intermediate phase of emptying were also significantly lower in the DU subjects than in controls (16.4 ± 2.5 versus 28.4 ± 4.8 min, $p<0.025$ and 20.8 ± 1.1 versus 27.4 ± 2.5 min, $p<0.0125$, resp.). In norma
subjects, ingested acid suppressed plasma gastrin below basal values at 15 min ($p<0.025$), and signif
cant suppression continued to the end of the study
In DU subjects, significant suppression ($p<0.05$) o
plasma gastrin concentration occurred 45 min after acid ingestion, and suppression lasted to the end
the experiment. Controls showed no significant elevation in mean plasma secretin level at any poi
but DU subjects demonstrated significant ($p<0.025$) elevation at 5 min after acid consumption. When the mean plasma secretin concentrations were calculated for the intermediate phase of gastric empyti
(process at steady rate) the increment in plasma secretin showed significant correlation with the rate at which acid left the stomach (in DU subject
$r=0.816$, $p<0.0025$ and in control, $r=0.688$, $p<0.01$)
The point where the regression lines intersect the abscissa represents a quantitative acid threshold for measurable secretin release. It occurred in D
subjects at 0.413 mmol/min and in controls at 0.02
mmol/min, $p<0.01$. The higher threshold in DU subjects suggests that defective secretin release at intermediate acid flow rates results in defective augmentation of the acid-neutralizing processes by secretin-stimulated pancreatic juice at high level
of acid production. The results show that DU subjects as a group discharge an acid load from the stomach more rapidly than do control subjects. Th
appearance of a quantitative threshold for secreti
release of about 0.3 acid mmol/min suggests that secretin acts in a reserve capacity, stimulating the flow of pancreatic bicarbonate only when high levels of acidity require it.

8262 GASTROESOPHAGEAL SPHINCTER PRESSURE AND SERUM GASTRIN: REACTION TO FOOD STIMULATION IN NORMAL SUBJECTS AND IN PATIENTS WITH GASTR
OR DUODENAL ULCER. (Eng.) Csendes, A.; Oster, M.
Brandsborg, O.; Moller, J.; Amdrup, E. (Hospital
J. Aquirre, Santos Dumont 999, Santiago, Chile). *Scand. J. Gastroenterol.* 13(3):363-368; 1978.

The effect of solid food on gastroesophageal sphi
pressure (GESP) and serum gastrin concentration (SGC) was studied in patients with gastric ulcers (GU), duodenal ulcers (DU), and in normal control
GESP and SGC measurements were made in the restin
state and then followed for 2 hr after the ingest
of a normal mixed meal (29 g of protein, 28 g of
and 2 g of carbohydrates), a potato meal (3 g prot
8 g fat, and 38 g carbohydrate), or an i.v. infus
of Aminosol (70% amino acids and 30% small peptid
total protein, 25 g). No significant differences
demonstrated in the basal GESP or SGC values amon
three groups. After the intake of the protein mea
GESP rose 2.6 ± 1.2 mm Hg/min in controls and 5.0

2.9 mm Hg/min in DU patients, while the SGC rose 19.5 ± 6.2 and 27 ± 7 pg/ml/min, resp. These nearly parallel increases are thought to be inter-related and due to the presence of intraluminal proteins in the upper gastrointestinal tract. The protein meal-stimulated GESP was significantly ($p<0.05$) higher than basal GESP from 60 to 100 min after eating (peak at 80 min in controls and at 60 min in DU patients). In GU patients, a decrease in GESP (-7.0 ± 1.4 mm Hg/min) and a rise in SGC (125 ± 41 pg/ml/min) occurred after protein meal ingestion. The decrease was significantly ($p<0.05$) lower than basal values from 60 to 100 min postprandially (peak decrease at 80 min). The increase in SGC was significant ($p<0.05$) in GU patients at 30 and 45 min, while in DU patients, it was significant ($p<0.05$) at 15, 30, and 45 min postprandially. There was no variation in SGC compared with basal values in any subject after ingestion of the potato meal or during the i.v. infusion of Aminosol. When the potato meal was given to two controls and two DU patients, the GESP decreased (peak decrease at 40 min, returning to basal values at 80 min). The i.v. infusion of Aminosol in a normal and a DU patient produced no GESP changes. The results show that the effect of protein food on GESP is different for GU and DU patients, possibly due to an alteration in the intrinsic properties of the specialized sphincteric muscle. The effect of food is mediated by proteins in the gastrointestinal tract.

SMALL INTESTINE

8283 PARAPROTEINEMIA IN NORMAL FAMILY MEMBERS OF EIGHT CASES WITH PRIMARY INTESTINAL LYMPHOMAS IN IRAQ. (Eng.) Alsabti, E. A. K. (Albaath Specific Protein Reference Unit, Baghdad, Iraq). *Oncology* 35(2):68-72; 1978.

The clinical and laboratory findings in eight patients with alpha-chain disease associated with primary intestinal lymphomas were analyzed, and the serum IgA level was determined in the families of these patients. The clinical, laboratory, radiological, and histopathological findings in the eight patients suggested malabsorption. Abdominal pain, diarrhea, and weight loss were present in all patients. The villous architecture was distorted in all patients; sparse crypts, pleomorphism and hypercellularity of the lamina propria, invasion of the muscularis mucosa, and lymphatic dilatation were present in six. The serum IgA levels ranged between 380 and 1,405 mg/100 ml. The serum IgG level was abnormally low (170-420 mg/100 ml) in all but one patient (1,120 mg/100 ml). The IgM levels ranged between 0 and 425 mg/100 ml. IgD levels were normal in all cases, ranging from 0 to 9.2 mg/100 ml. Of the 129 family members, 23 had abnormal IgA levels. This result suggests that these individuals should be carefully monitored for the development of intestinal lymphoma.

8284 CROHN'S DISEASE: "ITS GYNECOLOGIC ASPECT." (Eng.) Donaldson, L. B. (Medical Dental Bldg., Seattle, WA 98101). *Am. J. Obstet. Gynecol.* 131(2):196-202; 1978.

The medical records of 103 patients with gynecologic features of Crohn's disease are reviewed. The clinical history most frequently included signs and symptoms related to bowel obstruction. Specific signs and symptoms included abdominal pain in 63 cases; abscesses in 36 (13 pelvic, 11 perirectal, 8 perineal, 2 ischiorectal, 1 gluteal fold, and 1 epidural); tender adnexal mass in 28; rectal or perineal pain in 18; rectal bleeding in 12; vulvovaginitis, rectal fissure, or perineal ulcer in 8 cases each; right abdominal mass in 6; and dyspareunia in 4. The earliest signs and symptoms in some instances appeared to be unrelated to Crohn's disease and consisted of infections, ulcers, fissures, abscesses, and fistulas of the internal and external pelvic structures. Of 55 patients misdiagnosed, a large number had these prodromal gynecologic aspects of the disease. In over half of the 103 patients with Crohn's disease, intestinal obstruction was considered in the initial diagnosis. The diagnosis of the disease was first established at laparotomy in 23 of the 103 patients. The incorrect preoperative diagnoses in most instances were appendicitis (27), pelvic inflammatory disease (11), or ovarian cysts (5). There were 27 appendectomies performed, but there were no cases of acute appendicitis. The present study indicates no unfavorable effect of Crohn's disease on pregnancy; the effect of pregnancy on Crohn's disease appears to be minimal, with exacerbation of the disease occurring in only two patients in the immediate postpartum period. It is suggested that the gynecologic aspect of Crohn's disease should be considered in making a diagnosis, especially when abdominal pains and bowel complaints are present.

8285 JEJUNO-GASTRIC INTUSSUSCEPTION--GASTROSCOPIC DIAGNOSIS.

(Eng.) Varley, C. C.; Dyer, N. H. ("Stanhill," 34 Queens Rd., Melbourne, Victoria 3004, Australia). *Aust. N.Z. J. Med.* 7(5): 515-517; 1977.

The case of a patient in whom jejuno-gastric intussusception was diagnosed by gastroscopy is presented. The patient was a 76-yr-old woman who had undergone a Polya gastrectomy for pyloric stenosis complicating a duodenal ulcer 8 yr previously. She presented after developing colicky abdominal pain, projectile vomiting, and hematemesis. There was mild epigastric tenderness on examination. Gastroscopy revealed normal inflamed gastric mucosa of a Polya gastrectomy. At the stoma, the lumen of the afferent limb was patent and contained bile-stained fluid. The efferent limb lumen was filled with intussuscepted small bowel, which had a grossly swollen, engorged bleeding surface. The intussuscepted bowel extended nearly up to the hiatus. At laparotomy, the intussusception was reduced manually, and the patient had an uncomplicated recovery. Endoscopy is the method of choice to diagnose this uncommon, but important condition.

8286 ADAPTATIVE CHANGES IN THE SMALL INTESTINE FOLLOWING BYPASS OPERATION FOR OBESITY: A RADIOLOGICAL AND HISTOLOGICAL STUDY.

(Eng.) Solhaug, J. H.; Tvete, S. (Sjukhuset, 68500 Torsby, Sweden). *Scand. J. Gastroenterol.* 13(4):401-408; 1978.

Roentgenographic follow-up studies were made in seven patients before and at various intervals after jejunoileal bypass, to investigate adaptive changes to this procedure. Length measurements were made by a modified intubation technique, and intestinal transit time was estimated after a standard contrast meal. At surgery, 20 cm of proximal jejunum was anastomosed end-to-end to the distal 25 cm of ileum. With increasing observation time, a successive increase was observed in intestinal length both in the jejunal and ileal segments. One year after bypass, the mean growth of the functioning ileum was 100%, and the elongation of the jejunal segment was 50%. Eighteen months after the bypass, the mean growth values for the ileum and jejunum were 128% and 80%, resp. In serial films taken 4-6, 12, and 18 months after bypass, the diameter of both the functioning jejunum and ileum remained essentially unaltered. The mean increase in the diameter of the jejunum and ileum before and after bypass was approximately 40% and 50%, resp. The mean transit time of a test meal from the pylorus to the anastomotic level at 6, 12, and 18 months was 1.6 ± 0.6, 4.6 ± 6, and 4.8 ± 5 min, resp. The transit time from the anastomosis to the cecum was 38 ± 29, 55 ± 26, and 60 ± 28 min, resp. The postoperative gastric and functioning small intestinal emptying times were generally unaltered compared with preoperative findings. The mean increase in villous height in the functioning jejunum was 14% at 6 months after bypass and 55% after 12 months. In the ileum, the values were 32% and 66%, resp. In the bypassed ileum, the mean villous height decreased by 16% at 6 and 12 months. The observations suggest that there is an increase in intestinal absorptive surface following small intestinal bypass, which is due to dilatation and elongation of the functioning remnant as well as to an increase in villous height. An increase in transit time, permitting prolonged contact between nutrients and the absorptive intestinal surface, is probably a contributing factor in the leveling off of weight loss observed between 12 and 18 months after bypass.

8287 PEUTZ-JEGHERS SYNDROME: EXPERIENCE WITH TWENTY PATIENTS IN FIVE GENERATIONS.

(Eng.) McAllister, A. J.; Richards, K. F. (511 Medical Arts Bldg., Salt Lake City, UT 84111). *Am. J. Surg.* 134:717-720; 1977.

Experience with 20 patients in one family with the Peutz-Jegher's syndrome is reviewed, and the case report of a patient with an unusual presentation is given. The disease is characterized by pigmented spots on the lips and oral mucosa and intestinal polyposis. The intestinal polyps are hamartomas, and occur throughout the gastrointestinal system, with the heaviest incidence in the jejunum. In the family reported, which represents five generations, only three members were without symptoms. The clinical course of this syndrome is characterized by asymptomatic periods interspersed with complications such as intermittent cramping, abdominal pain, small intestinal intussusception, and hemorrhage. The patient whose case report is presented was unusual in that colonic intussusception was present. Examination revealed no abdominal masses, and bowel sounds were absent. Radiologic studies established the diagnosis of colonic intussusception. At surgery, 10 cm of the transverse colon was intussuscepted with a large leading polyp, measuring 5.5 x 4.5 x 4.0 cm, which was removed together with 11 cm of involved bowel. These observations suggest that intussusception can occur at any level of the gastrointestinal tract. The hematocrit should be checked every 6 months in patients with the Peutz-Jegher's syndrome to test for occult bleeding. X-ray films should be taken every 2 yr after the age of 10, and any polyps visualized in the stomach or colon should be removed endoscopically.

Malabsorption

04 STANDARDIZED ('TRIFIXED') DIET IN THE STUDY OF CHRONIC MALABSORPTION SYNDROMES.

ng.) Hylander, E.; Jarnum, S.; Keldsbo, I. L.;
ale, M. (Rigshospitalet, 2100 Copenhagen O, Den-
rk). *Scand. J. Gastroenterol.* 13(4):423-431;
78.

testinal absorption was studied in patients with
fferent types of malabsorption syndromes who were
aced on diets with fixed amounts of calcium, ox-
ate, and fat. The patients included 70 with
ohn's disease, 11 with ulcerative colitis, 40
o had undergone an intestinal bypass operation,
with nontropical sprue, 10 with short-bowel syn-
ome, and 3 with other gastrointestinal diseases.
e patients received 70 g of fat, 800 mg of cal-
um, and 200 mg of oxalate daily in their diet.
cal fat, ^{47}Ca absorption, ^{14}C-oxalate absorption,
d renal oxalate excretion were measured, and in
e majority of patients a ^{14}C-glycocholic acid
eath test was also performed. In 83 patients in
om calcium absorption was determined by whole-
dy counting and by the accumulation of absorbed
Ca in the skeleton of the underarm, ^{47}Ca absorp-
on was almost identical ($r=0.92$, $p<0.001$) by the
o procedures. ^{14}C-oxalate absorption and renal
alate excretion in the 138 patients in whom both
ocedures were carried out also correlated well
$=0.85$, $p<0.001$). Fecal fat and renal oxalate ex-
etion were weakly correlated ($r=0.63$, $p<0.001$),
t there was no correlation between fecal fat
d calcium absorption or between oxalate and cal-
um absorption. It is recommended that the "tri-
xed" regimen with absorption studies of fat, cal-
um, and oxalate be undertaken before treatment
r the reduction of steatorrhea or hyperoxaluria
for improvement of calcium absorption in chronic
labsorption syndromes.

05 SMALL-BOWEL MALABSORPTION AND GASTRO-INTESTINAL MALIGNANCY.

(Eng.) Collins,
M.; Hamilton, J. D.; Lewis, T. D.; Laufer, I.
cMaster Univ. Medical Center, Hamilton, Ontario,
nada). *Radiology* 126(3):603-609; 1978.

e cases of four patients with malabsorption and
strointestinal malignancies are presented. All
tients demonstrated histological and radiological
atures of celiac disease and showed improvement
gluten withdrawal. The first patient had been
ymptomatic for 27 yr after experiencing symptoms
malabsorption, diagnosed as tropical sprue. He
veloped diarrhea, steatorrhea, anorexia, leth-
gy, and weight loss, which resolved upon with-
awal of dietary gluten. A squamous cell carcin-
a of the middle third of the esophagus was dis-
vered 2 yr later; no abnormality could be
tected on the esophagrams taken 2 yr earlier.
e second patient had a childhood history of
liac disease but had been relatively asympto-
tic on a normal diet since the age of 15 yr.
the age of 47, he developed severe steatorrhea, weight loss, finger clubbing, and abdominal distention, and the symptoms did not improve on gluten withdrawal, even when prednisone was added to the regimen. A high serum IgA level was present, suggesting a lymphoma. Small bowel biopsy returned to normal and marked clinical improvement occurred when vincristine and cyclophosphamide were added to the regimen. A small bowel enema study suggested extrinsic ileal compression, and an unresectable, mesenteric, poorly differentiated reticulum cell sarcoma was discovered. The third patient presented with a 1-yr history of symptoms of malabsorption at age 74. Subtotal villous atrophy persisted, despite a 3-month period of gluten withdrawal. Following the removal of an *in situ* jejunal adenocarcinoma, there was marked clinical improvement while the patient was on a gluten-free diet, and a jejunal biopsy showed considerable improvement. The last patient, a 55-yr-old man, developed celiac disease that was initially responsive to gluten withdrawal; he became unresponsive with the development of pancreatic carcinoma. With a combination of prednisone and gluten withdrawal, he was once again rendered gluten-sensitive, as demonstrated by his marked clinical improvement and by the dramatic deterioration that occurred when gluten was accidentally reintroduced. It appears that there is an increased incidence of gastrointestinal malignancy in patients with celiac disease. These patients should have regular radiographic surveys.

8306 MALABSORPTION IN INFECTIOUS MONONUCLEOSIS.

(Eng.) LoIudice, T. A.; Lang, J. A. (Cedar-Locust Medical Pavilion, Ste. 206, 157 W. Cedar St., Akron, OH 44307). *Am. J. Gastroenterol.* 67(6):604-607; 1977.

The case of a patient in whom infectious mononucleosis was complicated by malabsorption is presented. The patient, a 23-yr-old man, presented with a fever of 40 C, cramping abdominal pain, nausea, vomiting, diarrhea, polyarthralgias, light-headedness, irritability, malaise, anorexia, and weight loss. A mono spot test was positive and a heterophil titer was 1:1,448. When diarrhea continued for longer than 1 week, further investigations were undertaken. The results of these included a d-xylose excretion (25 g p.o. dose) of 2.5 g/5 hr, a 72-hr stool fat of 36 g, and a duodenal aspirate that revealed no organisms. In addition, a small bowel roentgenographic series showed extensive thickening of mucosal folds with puddling of barium, and a jejunal biopsy revealed marked blunting of villi with an inflammatory infiltrate in the lamina propria. The patient responded to treatment consisting of i.v. fluid and electrolyte replacement, i.m. codeine, and bed rest. Two months after admission, a mono spot test was negative and the results of a small bowel series and a repeat small bowel biopsy had returned to normal. Malabsorption appears to be a rare complication of this disease.

8307 COMPLETE CLINICAL, HISTOLOGICAL, AND IMMUNOLOGICAL REMISSION IN A PATIENT WITH ALPHA-CHAIN DISEASE TREATED BY ORAL ANTIBIOTICS. (Fre.) Rambaud, J. C.; Piel, J. L.; Galian, A.; Leclerc, J. P.; Danon, F.; Girard-Pipeau, F.; *et al.* (Hopital Saint-Lazare, 107 bis, rue du Faubourg-Saint-Denis, F 75475 Paris Cedex 10, France). *Gastroenterol. Clin. Biol.* 2(1):49-61; 1978.

A case is presented of alpha-chain disease in a 17-yr-old Algerian boy who had no history of immunological disease in his family (parents and five siblings). Initial symptoms were fever, vomiting, diarrhea, and abdominal pain. All symptoms except diarrhea subsided at first, but latter grew progressively worse with weight loss, edema of lower limbs, and finally tetany. Rectal and gastric biopsies obtained by endoscopy suggested the diagnosis of alpha-chain disease (plasma cell infiltrations of mucosal crypts) that was confirmed by immunological studies. The patient was treated by various antibiotics (tetracycline, metronidazole, ampicillin, colistine, and amphotericine) over a 3-month period. After only 12 days on antibiotics, intestinal malabsorption improved and the abnormal IgA disappeared from the serum but not from the intestinal cellular infiltrate. Restoration of the severe magnesium depletion resulted in normal blood calcium levels and disappearance of tetany. A *Giardia lamblia* infection was cured at the same time. The complete remission of symptoms was confirmed by biopsy performed at laparotomy 6 months after end of antibiotic treatment. Proximal jejunal biopsy showed normal plasma cells with a moderate increase of the alpha-chain IgA cells compared with the normal state.

8308 SHORT-TERM GLUTEN CHALLENGE TEST IN CELIAC DISEASE. (Ita.) Mastella, G.; Trabucchi, C.; Mengoli, V.; Olivieri, D.; Rossi, F. A. (Ospedale Infantile Alessandri, Verona, Italy). *Minerva Pediatr.* 29(37):2235-2252; 1977.

An analysis of the short-term gluten challenge test in celiac disease is presented. Ninety-one children (aged 12 months-10 yr) were divided into three groups: 29 diagnosed as having celiac disease (group 1), 45 patients with chronic diarrhea of unknown etiology (group 2), and 17 with recurrent intestinal disturbances (group 3). All received gluten for 9-17 days either as commercial gluten (800 mg/kg intradermally/day) or in normal alimental form (10-25 g/day). The body weight, number and character of defecations, circumference of the abdomen, mood and physical activity, general clinical results, biopsy of the intestinal mucosa, xylose absorption test, and levels of IgA, IgG, IgM, and the C'3 complement fraction were monitored over a 20-day period. The condition of the intestinal mucosa was numerically evaluated over the range from 0-3 (grade 3 lesion) to 10-12 (normal mucosa). The average values before treatment were 5.29 (group 1), 7.55 (group 2), 9.24 (group 3), and after treatment were 3.48 (group 1, $p<0.05$), 6.87 (group 2), and 9.05 (group 3). The xylose absorption test showed positive but insignificant differences after treatment in 20/32 tests in grou 1, 21/45 tests in group 2, and 4/19 tests in group 3. Changes in the coefficient of absorption of fat (C.A.%) before and after treatment were 91.92 to 90.81 C.A.% in group 1, 93.91 to 94.75 C.A.% in group 2, and 96.58 to 97.13 C.A.% in group 3; positive changes occurred in 17/33 tests in group 1, 10/52 tests in group 2, and 1/19 tests in group 3. The daily weight of the feces increased from 77.03 g to 122.76 g, $p<0.01$ in group 1, from 88.37 to 89.73 in group 2, and from 97.71 to 99.26 in group 3. Differences between groups 1 and 3 were significant for all four tests ($p<0.01$); between groups 1 and 2 were significant for the condition of the intestinal mucosa ($p<0.001$), C.A.% of fat ($p<0.01$), and weight of feces ($p<0.05$); and betwee groups 2 and 3 were significant only for the xylos test ($p<0.05$). On the basis of the gluten test, the diagnosis was celiac disease in group 1 patients, 6/45 group 2 patients, and 0/17 group 3 pa tients; no diagnosis could be reached on this basis in 4/29, 15/45, and 1/17 in groups 1, 2, and 3, resp. The variability of results with time in some patients suggests that the response to gluten is not constant, thus leaving a margin of uncertainty in a number of patients suspected of celiac disease. The results of the measurements of the immunoglobulins and C'3 fraction suggest that gluten does not have an immunogenic effect in these patients. It was concluded that the short-term gluten test is well tolerated in these patients and remains a useful test until a more definite one is found.

8309 TOLERANCE TO LACTOSE AMONG LACTASE-DEFICIENT AMERICAN INDIANS. (Eng.) Newcomer, A. D.; McGill, D. B.; Thomas, P. J.; Hofmann, A. F. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Gastroenterology* 74(1): 44-46; 1978.

LARGE INTESTINE

17 SYSTEMIC PROPHYLAXIS WITH DOXYCYCLINE IN
SURGERY OF THE COLON AND RECTUM. (Eng.)
jer, H.; Wetterfors, J. (Regionsjukhuset, S-581
Linkoping, Sweden). *Ann. Surg.* 187(4):362-368;
78.

prospective double-blind study on the effects of
xycycline as a prophylactic antimicrobial in elec-
ve colonic surgery was carried out in 118 patients.
fty-eight patients received 200 mg of doxycycline,
o., and 60 received placebo, 4-6 hr before surgery;
0 mg of doxycycline or placebo was given daily for
days postoperatively. A significantly lower inci-
nce of abdominal wound sepsis was seen in the
tients treated with doxycycline than in controls
.6 versus 41.5%, $p<0.001$). Abdominal septic
mplications of grade 3 and 4 in severity were
ss frequent in the treatment group ($p<0.01$).
croscopic peritoneal contamination occurred with
e same incidence in both groups but the rate of
sociated wound or intra-abdominal sepsis dropped
om 79% in the controls to 33% in the treated group.
en the wound culture was negative upon closure,
xycycline treatment caused a significant ($p<0.002$)
crease in the rate of abdominal wound sepsis.
xycycline treatment significantly reduced the rate
abdominal sepsis in malignant disease to 17%
om 70% in the controls ($p<0.001$), and significantly
duced the rate of abdominal sepsis in both strictly
tra- and mainly extraperitoneal procedures ($p<0.01$
both cases). Perineal infection occurred in 20%
patients in the doxycycline-treated patients and
47% of the controls; in the former group, it was
e sole septic complication, whereas in the latter
oup, the infection was combined with some type of
dominal sepsis. Doxycycline treatment also re-
ced the rates of urinary tract infections and
lmonary complications ($p<0.02$ and $p<0.04$, resp.).
ne of the doxycycline-treated patients required
peat laparotomy due to septic complications,
ereas eight patients in the control group required
rther surgery for sepsis. The results indicate
at doxycycline treatment significantly reduces
both the incidence and severity of postoperative sepsis in elective colorectal surgery.

8318 RISKS OF SURGERY OF THE GASTROINTESTINAL TRACT AFTER RADIATION OF THE ABDOMINAL AND PELVIC CAVITIES. (Fre.) Mendes da Costa, P.; Gerard, A. (Institut Jules-Bordet, 1, rue Heger-Bordet, 1000 Brussels, Belgium). *Ann. Chir.* 31(10):866-870; 1977.

Two distinct groups were observed for complications after surgery preceded by radiation of the abdominal or pelvic cavities. Group I was composed of 47 patients who underwent amputation of the rectum by the abdomino-perineal route for adenocarcinomas. This group had been treated at random with 3,450 rads of radiation over a 19-day period with surgery following within 8 days of the last radiation treatment. Alternative random treatment was chemotherapy with 5-fluorouracil (1,500 mg/m^2) 4 days prior to surgery. Group II was composed of 42 patients all of whom underwent surgery of the gastrointestinal tract including colostomy of the rectum (14), resection and anastomoses (4), or liberation of adhesions of the small intestine (2), and resection and anastomoses or colostomy of the colon (8). These patients had been treated with 4,500-6,000 rads previously with an average delay between radiotherapy and surgery of 13.3 months. In 28/42 patients in group II, surgery was necessitated by a radiation lesion of the small intestine, colon, or rectum; in 13 patients, surgical intervention was performed because of residual or recurrent neoplasm. There were five postoperative deaths in group I and seven postoperative deaths in group II. Complications in group I included cystitis (14), infection of the perineum (11), abdominal abscess (5), necrosis of the colostomy (3), obstruction of the intestine (4), and a small intestine fistula (1). Complications in group II included infection (19), abscess (7), failure of anastomoses (7), intestinal obstruction (5), fistula of the digestive tract (4), paralytic ileus (2), and necrosis of the colostomy (2). It is concluded that utero-ileal anastomoses are contraindicated in previously irradiated patients, but intestinal anastomoses may be performed if sufficient collateral circulation is present.

8319 NEONATAL SMALL LEFT COLON SYNDROME: ITS RELATIONSHIP TO AGANGLIONOSIS AND MECONIUM PLUG SYNDROME.

(Eng.) Berdon, W. E.; Slovis, T. L.; Campbell, J. B.; Baker, D. H.; Haller, J. O. (Babies Hosp., 622 W. 168th St., New York, NY 10032). *Radiology* 125(2):457-462; 1977.

To clarify whether meconium plug syndrome, colon inertia, and neonatal small left colon syndrome can be distinguished from aganglionosis of the splenic flexure on radiographic and clinical grounds without recourse to rectal biopsy, experience with colon inertia and neonatal small left colon in 11 infants was reviewed and compared with other published reports and cases obtained by a hospital survey. Contrast enema studies of patients with colon inertia and those with small left colon syndrome were identical, showing distended loops of small bowel, right colon, and transverse colon with a sharp transition at the splenic flexure to a left-sided microcolon with a diameter of ≤1 cm; the rectum could be distended to a caliber of 2-3 cm while administering the enema. These radiographs were also identical to most of those published in cases of meconium plug syndrome; moreover, in many cases, meconium had been passed prior to the enema or else no plug was demonstrated. While the clinical presentation of these foregoing probably identical syndromes may be quite similar to that of aganglionosis of the splenic flexure (abdominal distention, full-term status, difficulty in passing meconium) and while all may have plain radiographic evidence of distended loops with frequent air/fluid levels and contrast enemas showing a transition zone, aganglionosis extending to the splenic flexure is readily differentiated from functional left-sided microcolon by the fact that aganglionic bowel is rarely reduced in caliber compared with normal bowel, whereas the microcolon has a caliber <1 cm. Whether or not to obtain a rectal biopsy in such cases must be based on the clinical response to the initial cleansing enemas and the subsequent course.

8320 SIGNIFICANCE OF CYTOLOGICAL INVESTIGATIONS IN THE DETECTION OF NEOPLASTIC CHANGES OF THE RECTOSIGMOID.

(Ger.) Miczban, I.; Feher, M. (Poliklinika, Janos Korhaz, Budapest, Hungary). *Tijdschr. Gastroenterol.* 20(4):237-250; 1977.

Six hundred eleven consecutive exfoliative cytological investigations of the rectosigmoid were performed in 578 patients. The patients were also examined histologically and clinically. The cytology was negative in 536 cases, which all were found to be normal histologically. The cytology was doubtful in 13 cases; ulcerative colitis was diagnosed histologically in 11 of these cases and tumor in 2. Cytology showed polyp in 18 cases; th histological examinations of these patients revealed ulcerative colitis in 1 and polyp in 17. The cytology showed malignant changes in 11 cases; one of them was diagnosed histologically as ulcerative colitis, another as polyp, and 9 as tumor. The cytology showed definitely malignant changes in 9/11 histologically confirmed cases of tumor, but it was doubtful in the other 2 cases. All tumors were operable. The findings indicate the great diagnostic value of exfoliative cytology of the rectosigmoid, especially in combination with fiber rectoscopy.

8321 MULTIPLE CARCINOMAS OF THE LARGE BOWEL: A NATURAL EXPERIMENT IN ETIOLOGY AND PATHOGENESIS.

(Eng.) Enker, W. E.; Dragacevic, (Pritzker Sch. Medicine, Chicago, IL). *Ann. Surg* 187(1):8-11; 1978.

Theories concerning bile acids in colon carcinogenesis were tested by assuming that if bile acid were involved in colon cancer, the incidence of left-sided second primary cancers in patients wit metachronous large bowel cancer would be higher than the incidence of right-sided cancers in patients undergoing an initial left colectomy. Of 121 patients with two or more large bowel cancers 56.2% presented with synchronous lesions, while the other 43.8% presented with metachronous (nonsimultaneous) lesions. Of the patients with meta chronous large bowel cancer, 28 of 47 had their first lesion on the left side; 13 patients had the first lesion on the right side, while the remaining 6 had the first lesion in the transverse colon. Of the 28 patients who had their first resection on the left side, 12 subsequently developed their second primary carcinoma on the right side. Of the 28 patients who had their fir resection on the left side, 13 developed their second primary lesion in the remaining portion of the left side. In contrast, of the 13 patients w had their first resection on the right side of th colon, 10 developed a second lesion in the left side of the colon. Thus, the incidence of second primary carcinomas in patients who first underwent an initial right-sided resection was much higher than the incidence of right-sided cancers in patients undergoing initial left colectomies, and was also higher than the initial incidence of left-sided lesions. These results support the concept that increased delivery of bile acids to the colon may play a role in tumor pathogenesis.

8322 FECAL CONSTITUENTS OF A HIGH-RISK NORTH AMERICAN AND A LOW-RISK FINNISH POPULATION FOR THE DEVELOPMENT OF LARGE BOWEL CANCER.

(Eng.) Reddy, B. S.; Hedges, A.; Laakso, K.; Wynder, E. L. (Naylor Dana Inst. for Disease Prevention, American Health Foundation, Valhalla, NY 10595). *Cancer Lett.* 4(4):217-222; 1978.

To elucidate the role of dietary factors in the

logy of large bowel cancer, dietary composi-
and feces collected in rural Kuopio, Finland
ow-risk population area for this cancer) and
he New York metropolitan area (a high-risk
lation area for this cancer) were studied.
oth populations, the average daily intake
at and protein was essentially the same,
the sources of fat came principally from
in the New York population and from milk
other dairy products in Kuopio. Bile acid and
ral sterol levels and the β-glucuronidase ac-
ty of the stool samples was measured. A three-
greater output of feces ($p<0.05$) was found in
io compared to New York, possibly due to a
intake of fiber-rich cereal products. The
l bacterial β-glucuronidase activity/mg dry
s was lower in Kuopio than New York (18.6 ±
versus 69.3 ± 15.8 μg product formed/4 hr),
the total daily output of this enzyme activity
the same for both groups (1,122 ± 158 and 1,545
3 x 10^{-3} μg product formed/day). A signifi-
ly lower ($p<0.05$) concentration of secondary
acids, such as deoxycholic, lithocholic, urso-
ycholic, and 12-ketolithocholic acids, was
d in Kuopio. These bile acids have been found
ct as colon tumor promoters in animals. The
fecal bulk noted in Kuopio diluted both the
l β-glucuronidase activity and the fecal sec-
ry bile acids. The daily excretion of neutral
ols was higher in Kuopio than in New York.
results suggest that diets low in meat and
in fiber coupled with high fecal bulk in
and may protect against colon cancer by di-
ng tumorigenic compounds that come in direct
act with the colon mucosa.

THE ROLE OF 5-FLUOROURACIL AS AN ADJUVANT TO THE SURGICAL TREATMENT OF LARGE BOWEL
ER. (Eng.) Grage, T. B.; Metter, G. E.; Cor-
, G. N.; Strawitz, J.; Hill, G. J., III; Fre-
, R. W.; *et al. In: Adjuvant Therapy of Can-*
(Amsterdam: Elsevier/North-Holland Biomedical
s): 259-263; 1977.

effect of adjuvant chemotherapy with 5-fluor-
cil (5-FU) upon survival and the recurrence
was studied in 282 patients with colorectal
inoma, of whom 204 underwent curative resec-
and 78 underwent palliative resection. Chemo-
apy was started within 30 days after surgery
consisted of i.v. 5-FU (12 mg/kg/day x 4 and
6 mg/kg on alternate days x 5, followed by 12
g/week for 1 yr). Follow-up ranged from 3
hs to 65 months with a median of 30 months.
he curative group, survival continued to be
rately more favorable in the 5-FU treatment
p, although the difference was not significant
.09). However, the treatment group had a sig-
cantly longer disease-free interval, as deter-
d by plotting a disease-free interval curve,
g the Kaplan-Meier life table method ($p=0.045$).
survival and disease-free interval were sig-
cantly better for patients with carcinoma of
colon versus rectum ($p=0.038$ and 0.027, resp.).
atients with rectal carcinoma, both survival
and disease-free interval were significantly better with chemotherapy ($p=0.024$ and $p=0.037$, resp.). The disease-free interval for patients with lymph node metastases was significantly longer for those on chemotherapy ($p=0.018$). There was no significant difference in survival between the patients who underwent palliative or curative resection. However, the asymptomatic interval in the chemotherapy group was slightly longer ($p=0.027$). It is concluded that the treatment benefit following 5-FU administration as an adjuvant to surgical treatment of colorectal cancer is small, mainly seen in prolongation of the disease-free interval and confined to patients with either lymph node metastasis or patients with rectal carcinoma.

8324 VILLOUS TUMORS OF THE RECTUM AND COLON: DIAGNOSTIC AND THERAPEUTIC PROBLEMS AND STATISTICS ON 78 CASES.

(Fre.) Delile, P.; Marche, C.; Edelmann, G. (Hopital Bichat, 170, Bd Ney, 75018 Paris, France). *Ann. Chir.* 31(10): 829-842; 1977.

Among 78 patients with villous tumors of the rectum and colon, the histological diagnosis was purely villous tumors in 59, villous polyadenomas in 11, and adenocarcinomas with villous processes in 8. The purely villous tumors are defined as those consisting only of epithelium; however, they can be sessile (45), nonprotruding (6), or in the form of polyps (8). Villous polyadenomas consist of benign tumors of glandular and epithelial tissue. Excluding the villous adenocarcinomas, there were 31 benign villous tumors and 7 suspect and 32 definitely malignant tumors. All the villous tumors of the colon and rectosigmoid (21) whether malignant or benign, were resected by the abdominal route, and there were no postoperative complications. A recall period of 6 months to 17 yr on these patients revealed two lost to follow-up and no recurrences, even though six patients had had stage II, III, or IV tumors. Various surgical procedures were used to extirpate 34 villous tumors of the rectum (21 benign, 13 malignant) implanted within 12 cm of the anal margin: transanal tumorectomy (27, of which 12 required further surgery or electrocoagulation for recurrence), trans-sacral tumorectomy (3), abdomino-transanal amputation of the rectum (2), and abdominoperineal amputation of the rectum (2), with 3 operations for recurrence. The recurrences always followed incomplete excision. It is stated that villous tumors of the rectum can always be treated by extensive local excision rather than rectal amputation unless there is obvious invasion of the submucosa or tumor degeneration.

8325 AGE-RELATED CHANGES IN THE COLONIC BLOOD SUPPLY: THEIR RELEVANCE TO ISCHAEMIC COLITIS.

(Eng.) Binns, J. C.; Isaacson, P. (Southampton Univ. Hosp., Southampton SO9 4XY, England). *Gut* 19(5):384-390; 1978.

The anatomy of the colonic circulation was studied by performing postmortem angiograms in 37 subjects of different ages (neonate-92 yr) to determine if age-related changes in the colonic blood supply are relevant to ischemic colitis due to nonocclusive mesenteric ischemia. Radiopaque material was injected into the superior mesenteric artery (SMA) or inferior mesenteric artery (IMA). Good filling of the colonic circulation was obtained in 23 of the 29 cases in which the SMA was injected. Of 13 cases of occlusion or severe stenosis of the IMA ostium, complete filling of the colonic circulation was obtained in 9. Good filling of the colonic circulation was obtained in five of the eight cases in which the IMA was injected. The diameter of the marginal artery decreased from right to left. The average diameters of the artery at the ascending colon, transverse colon, splenic flexure, and descending colon were 1.6 mm, 1.13 mm, 0.94 mm, and 0.89 mm, resp. In adults, the diameters were constant over the wide range of ages. In 17 of the 37 colons, the artery was continuous and specifically, no interruption or unusual narrowing was seen at the splenic flexure. In 11 other colons, the artery had been damaged during removal of the colon but appeared to be continuous. In young subjects, the long colic arteries were straight with almost complete absence of tortuosity. Regression lines calculated from graphs plotting tortuosity against age indicated that tortuosity of these vessels increases significantly with age ($p<0.01$ in transverse colon, $p<0.02$ at splenic flexure, $p<0.05$ in ascending colon, and $p<0.01$ in descending colon). These results demonstrate a distinct age-related tortuosity of the long colic arteries, which could account for the increasing incidence of ischemic colitis with age. No anatomical basis for the higher incidence of left-sided involvement was found, and no critical point in the arterial circulation at the splenic flexure was demonstrated.

8326 MANOMETRIC INVESTIGATION OF THE ANAL CANAL IN PRIMARY CHRONIC FISSURE BEFORE AND AFTER DILATATION OR SPHINCTEROTOMY. (Ger.) Fischer, M.; Thermann, M.; Hamelmann, H. (Chirurgische Universitatsklinik, Robert-Koch-Strasse 8, D-3550 Marburg, W. Germany). *Chirurg* 49(2): 111-113; 1978.

Manometric investigations were performed in the anal canal before and 6 months after stretching or sphincterotomy in 28 patients with primary chronic fissure of the anal canal. Compared with a proctologically healthy control group and with the values measured before intervention, the length of the functional anal canal did not change significantly after stretching and sphincterotomy, but the position of the maximum resting pressure shifted orad, though remaining within 1-2 cm from the anocutaneous border. The maximum resting pressure in the anal canal was significantly higher during the chronic fissure than either after stretching and sphincterotomy ($p<0.001$) or in the controls but there was no significant difference from the controls after the intervention. The findings indicate that an elevated resting anal pressure is one of the pathogenetic mechanisms in the development of primary chronic fissure and that it is eliminated efficiently by stretching or sphincterotomy.

LARGE INTESTINE

Ulcerative Colitis

381 A RADIOLOGICAL AND PATHOLOGICAL CORRELATION OF THE MUCOSAL CHANGES IN ULCERATIVE
OLITIS. (Eng.) Bartram, C. I.; Walmsley, K.
St. Mark's Hosp., City Rd., London EC1V 2PS, Eng-
and). *Clin. Radiol.* 29(3):323-328; 1978.

he results of double-contrast barium enema (DCBE)
n 37 patients with ulcerative colitis were compared
ith the pathological appearance of resected colonic
pecimens from each of these patients to assess
he value of DCBE in this disease. DCBE was carried
ut without bowel preparation in 29 patients. Total
olitis was demonstrated macroscopically in 26 re-
ected specimens and histologically in 32. Radio-
ogical and pathological agreement of the extent of
he disease was present in 12 patients with total
olitis and in 5 patients with subtotal colitis.
n 20 patients, total colitis was diagnosed histo-
ogically, but radiologically the disease extended
roximally to the hepatic flexure in 8, to the
ransverse colon in 6, to the splenic flexure in 4,
nd to the descending colon in 2. The radiological
ppearance was placed into one of the following
ategories by two observers: granular fine (GF),
ranular coarse (GC), coarse surface irregularity
CSI), and mucosal excrescences (ME). The patho-
ogical appearance was graded according to the
ollowing categories: type 1, rough granular sur-
ace with no obvious defects; type 2, a similar
texture but with small surface defects; type 3, severe disruption of the surface due to ulceration; and type 4, the presence of mucosal tags. Observer agreement was present in 74% of the cases classified as GC and in 86% of cases classified as CSI; agreement was poor with GF and ME. Where observer agreement was present, the radiological and pathological classifications were well correlated. GF was associated with type 1 pathological appearance in 75%, GC with type 2 in 74%, and CSI with type 3 in 85%. With ME the numbers were too small for a valid conclusion. With qualifications, the DCBE without bowel preparation provides useful information as to the extent and severity of ulcerative colitis.

8382 LEUCOCYTE MIGRATION TEST WITH AUTOLOGOUS COLONIC MUCOSA AS ANTIGEN IN PATIENTS WITH ULCERATIVE COLITIS. (Eng.) Astrup, L.; Rasmussen, S. N.; Binder, V. (Frederiksberg Hosp., Ndr. Fasanvej 59, 2000 Copenhagen F, Denmark). *Scand. J. Gastroenterol.* 12(8):951-955; 1977.

The immunological parameters of ulcerative colitis (UC) were evaluated by the leukocyte migration agarose technique (LMAT, Clausen's technique) using the patient's own colonic mucosa as a possible antigen. To determine if a possible autohypersensitivity was specific to colonic mucosa, the results were compared with those obtained using autologous skin and buccal mucosa. The migration of peripheral WBC was studied in 16 untreated UC patients (5 inactive, 7 moderately active, 4 very active). Twelve patients with peptic ulcer, irritable colon, or hemorrhoidal tumors served as controls. The final concentration of protein in the three types of antigen solution was standardized to 100 μg/ml medium. The final concentration of WBC in the test solutions was 2.8×10^8/ml. The migration index (MI, ratio of area with antigen to the area without antigen) for UC patients and for controls was 1.02 ± 0.08 and 1.03 ± 0.13, resp., with rectal mucosa as antigen, 1.04 ± 0.08 and 1.07 ± 0.14, resp., with skin as antigen, and 0.98 ± 0.10 and 1.02 ± 0.09, resp., with buccal mucosa as antigen. The MI was considered to be within normal limits in all patients, regardless of the antigen used. No significant differences were demonstrated among the MI values. No correlation between the MI and the clinical activity of UC was demonstrated. The authors conclude that no antigen activity of autologous colon mucosa, buccal mucosa, or skin was demonstrable in UC by means of the LMAT but question whether the concentration of antigen used in the study was sufficient.

8383 FLUORESCENT ANTI-COLONIC AND E. coli ANTIBODIES IN ULCERATIVE COLITIS. (Eng.)

Marcussen, H. (Bispebjerg Hosp., Bispebjerg Bakke, 2400 NV, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 13(3):278-281; 1978.

To examine the possibility that *Escherichia coli* lipopolysaccharide (LPS) cross-reacting antigens induce autoimmunization to colon antigens in patients with ulcerative colitis (UC), the antigenic similarities between *E. coli* and colon mucosa from guenons and from rats were investigated and several *E. coli* serotypes were compared with each other antigenically using an indirect immunofluorescence technique. Sera from eight patients with UC yielded positive staining of goblet cells (4 with both antigens, 2 with guenon antigen only, and 2 with rat antigen only); sera from two patients were entirely negative, as were sera from five hospital controls. When the 10 patient sera were applied to agar preparations of 13 *E. coli* O group strains, there was 1 reaction with the O 1 serotype, 4 with the O 2 serotype, 3 with the O 8 serotype, and 5 with the O 14 serotype; there were 13 doubtful reactions between patient sera and 8 other *E. coli* O group serotypes. The only reactions among the control sera were two doubtful reactions, one each to serotypes O 8 and O 25. The fluorescent-staining activity of the seven patient sera that had reacted with *E. coli* antigens O 2, O 8, and O 14 was abolished by absorption with sediments of the corresponding bacteria. The strength of the immunofluorescence reaction was found to decrease as the sera were progressively diluted from 1:2 to 1:32. The results indicate that antigens from colon mucosa share antigenic determinants with some *E. coli* bacteria or bacterial components (possibly LPS).

8384 IgG MYELOMA PRESENTING AS ULCERATIVE COLITIS. (Eng.)

Haeney, M. R.; Ross, I. N.; Thompson, R. A.; Asquith, P. (East Birmingham Hosp., Birmingham B9 5ST, England). *J. Clin. Pathol.* 30(9):862-867; 1977.

To document the association of ulcerative colitis and myeloma, the cases of two elderly patients (a 63-yr-old man and a 61-yr-old woman) who presented with profuse bloody diarrhea and weight loss are discussed. Sigmoidoscopy revealed a uniformly edematous, hyperemic rectal mucosa with mucus and contact bleeding in the man and a granular, edematous rectal mucosa with mucopus and severe contact bleeding in the woman. Barium enema revealed loss of sigmoidal mucosal pattern, poorly distensible rectum, and increased rectosigmoid space in both patients. Rectal biopsies showed nonspecific proctitis, infiltration by lymphocytes and polymorphonuclear leukocytes, and morphologically normal plasma cells in the man and active nonspecific proctitis, increased cellularity and polymorphonuclear leukocytes in the lamina propria, early crypt abscess formation, and no evidence of amyloid in the woman. Bone marrow histology in the man revealed atypical plasma cells showing nuclear immaturity of which 18-20% were IgG-staining and <1% were IgA- or IgM-staining by immunofluorescence (IF) and in the woman it showed atypical plasma cells forming clumps of which 10% were IgG-staining by IF; the woman's plasma cells were multinucleate and pleomorphic with prominent nucleoli. Both patients had monoclonal IgG serum paraprotein with free light chains (kappa in the man, lambda in the woman) in th urine. Both patients were treated with salazopyrine and steroid retention enema for the ulcerative colitis. Cyclophosphamide and prednisolone therapy (varying doses)was initiated in the male patient, ar this therapy led to an improvement in both gastrointestinal disease and myeloma. Specific treatment for the myeloma was withheld in the second patient. Because the etiology of ulcerative colitis is unknown, it is difficult to assess the relation between it and IgG myeloma; the decreased resistanc to infection that occurs during IgG myeloma may increase the potential for invasion by hypothetical microorganisms. It is suggested that a diagnosis of myelomatosis should be considered in elderly patients presenting with ulcerative colitis.

8385 A CONTROLLED COMPARISON OF CORTICOTROPIN AND HYDROCORTISONE IN TREATMENT OF SEVERE PROCTOCOLITIS. (Eng.)

Powell-Tuck, J.; Bucknell, N. A.; Lennard-Jones, J. E. (St. Mark's Hosp., City Rd., London EC1V 2PS, England). *Scand. J. Gastroenterol.* 12(8):971-975; 1977.

The effectiveness of corticotropin (ACTH) and hydr cortisone in the treatment of severe proctocolitis was compared using parenteral doses of the drugs arranged to give similar blood cortisol levels.

ixteen patients with confirmed proctocolitis
ere studied in a 7-day trial. Seven patients
ere treated with one daily i.m. injection of 80
 of ACTH gel. Nine patients received a constant
nfusion of hydrocortisone hemisuccinate, 400 mg/
4 hr. Three patients receiving hydrocortisone
equired a reduction of dose because of side-effects.
he two groups were comparable regarding the ex-
ent, severity, and previous treatment of the dis-
ase. Ten patients had received prior treatment
ith oral steroids immediately before entering
he study (hydrocortisone, 6; ACTH, 4). Nine pa-
ients were discharged on medical treatment (hy-
rocortisone, 6; ACTH, 3), one had elective sur-
ery after a good response to hydrocortisone
reatment, and six required colectomy after show-
ng no improvement on medical treatment (hydro-
ortisone, 2; ACTH, 4). The mean length of hos-
ital stay was 30 days in the hydrocortisone
roup and 40 days in the ACTH group. The measured
lasma cortisol levels were comparable except
mmediately prior to ACTH injection, when the
evels in the ACTH patients were significantly
$p<0.01$) lower than in the hydrocortisone patients.
o correlation was found between the plasma
ortisol levels and the observed therapeutic re-
ponse. The higher incidence of side-effects
ith hydrocortisone treatment appeared to be
elated to the high sustained cortisol levels
ver the 24-hr period. Patients who had received
rior treatment with prednisolone immediately be-
ore entering the study had a lower response rate
5/10) to medical treatment than did those who
ad not been previously treated (5/6). Although
he results do not suggest a major advantage for
ither treatment, the trend favors corticosteroid
herapy over ACTH in the treatment of acute colitis.
he parenteral administration of a synthetic gluco-
orticoid such as prednisolone (60 mg equivalent
o 300 mg of hydrocortisone) may be the treatment
f choice.

8396 THE ROLE OF CAERULEIN IN TESTS OF EXOCRINE PANCREATIC FUNCTION.

(Eng.) Cavallini, G.; Mirachian, R.; Angelini, G.; Vantini, I.; Vaona, B.; Bovo, P.; *et al.* (Clinica Medica III, Policlinico di Borgo Roma, Verona, Italy). *Scand. J. Gastroenterol.* 13(1):3-15; 1978.

The results of exocrine pancreatic function tests using rapid i.v. injection of secretin (1 clinical U/kg) plus cerulein (100 ng/kg) or cholecystokinin (1 or 2 Ivy Dog U/kg) were compared with those in which a continuous infusion was used. Sixty-three controls and 69 patients with chronic pancreatitis were placed in one of the above groups. Duodenal juice was collected for two and four 30-min periods in the subjects receiving the i.v. injection and the infusion, resp. Significant differences in volume secretion and bicarbonate and enzyme secretion were found in the patients as opposed to the controls at 30 min following the rapid i.v. injection of either secretin plus cerulein or secretin plus cholecystokinin. However, pancreatic stimulation was submaximal, and there was marked overlap between individual values of the parameters of pancreatic function in the patients and controls. Side-effects (diarrhea, upper right abdominal pain, and flushing) were noted in four patients who received secretin plus cerulein by i.v. injection. Better differentiation between normal and abnormal pancreatic function was provided by the continuous infusion of secretin and cerulein or secretin and cholecystokinin; the infusion of either combination produced similar results except in the case of volume. No side-effects were observed.

8397 PANCREATIC ASCITES.

(Fre.) Lienhard, P.; Hay, J. M.; Maillard, J. N. (Hopital Louis-Mourier, 92701 Colombes Cedex, France). *Chirurgie* 28(5):379-380, 383-384, 387-390; 1978.

The diagnosis and treatment of pancreatic ascites (defined as massive and recurring ascites occurring in the course of an isolated chronic pancreatitis) are discussed, and six cases are reported. Four of the patients had pseudocysts of the pancreas, and fluid was escaping into the peritoneal cavity as a result of rupture of the cyst. The pseudocysts were usually secondary to chronic pancreatitis in alcoholics (3/4 patients in this series). Two of these patients were treated by cystogastrotomy and two by splenopancreatectomy; a death caused by acute respiratory insufficiency 8 days postoperatively was the only treatment failure. The fifth patient had a small fistula on the head of the pancreas that developed after a partial gastrectomy for a duodenal ulcer; the pancreatic ascites was cured by insertion of an external drain (case does not fit the definition). The sixth patient had chronic pancreatitis attributed to alcoholism; however, no communication between the pancreas and the peritoneal cavity was seen at exploratory laparotomy. This patient did not have a recurrence of the ascites after the peritoneal cavity was drained a second time. The presence of chronic pancreatitis is not known in about 25% of patients with pancreatic ascites. Definitive diagnosis can be made by x-ray identification of the pseudocyst, presence of high levels of amylase in the ascitic fluid, and presence of bisalbumin in serum and ascitic fluid. Other treatment besides surgery may be the use of diuretics, steroids, antienzymes, and radiotherapy.

8398 ANGIOGRAPHIC EVALUATION OF GASTROINTESTINAL HAEMORRHAGE COMPLICATING PANCREATIC DISEASE.

(Eng.) Cosgrove, H.; Legge, D.; O'Connell, F. X.; Weir, D. (Mater Hosp., Dublin, Ireland). *Clin. Radiol.* 29(3):289-293; 1978.

The role of angiography in the management of gastrointestinal hemorrhage is discussed in relation to seven patients with gastroesophageal varices due to splenic or portal vein obstruction. Angiographic studies included celiac, superior mesenteric, splenic, and left gastric injections. In all cases, angiographic findings were confirmed at operation or at post-mortem examination. Five of the patients had pancreatitis and two had carcinoma. All but two of them had developed complications of pancreatic disease including pseudocyst, abscess, biliary obstruction, or pancreatic insufficiency. Such complications present a risk for the development of splenoportal hypertension and variceal bleeding. Five patients had occlusion or compression of the splenic vein and two had portal vein occlusion. Both patients with portal vein obstruction and two of those with splenic vein obstruction experienced acute and massive gastrointestinal bleeding. In three cases the bleeding resulted from the varices, and in one case, it resulted from tumor invasion into the duodenum. Endoscopic examination of two patients with splenic vein occlusion showed blood in the gastroesophageal region and excluded other causes of hemorrhage. One patient died; the other had a splenectomy based on angiographic demonstration of the source of the bleeding, and no further bleeding was experienced. In a patient with portal vein obstruction, endoscopy revealed blood in the pylorus of the stomach, and angiography showed that the source of the bleeding was the transverse pancreatic artery in the region of the head of the pancreas, due to mucosal erosion from carcinoma. The varices had not bled. Surgical resection of the duodenum and part of the tumor prevented further hemorrhage. The authors conclude that angiographic evaluation may be indicated in any patient with established or complicated pancreatic disease and that selective visceral angiography is essential for the proper management of these patients when gastrointestinal hemorrhage occurs.

8399 EVALUATION AND FOLLOW-UP OF PANCREATIC ARTERIOGRAMS. A NEW ROLE FOR ANGIOGRAPHY IN THE DIAGNOSIS OF CARCINOMA OF THE PANCREAS.

(Eng.) Herlinger, H.; Finlay, D. B. L. (St. James' Univ. Hosp., Leeds, England). *Clin. Radiol.* 29(3): 277-284; 1978.

The use of pancreatic angiography in the diagnosis

f pancreatic carcinoma was evaluated by examining
rteriograms for 103 patients (35 of whom had car-
inoma). There were three false-negative and seven
alse-positive diagnoses of carcinoma, giving an over-
ll accuracy rate of 90.3%. After reviewing the films
etrospectively, only one false-negative and one false-
ositive case could not be identified. Among the
ive periampullary carcinomas, the arteriogram
n one case presented as a small avascular area
ith only slight serpiginous encasement of sur-
ounding small vessels; another showed smooth en-
asement and displacement of the gastroduodenal
rtery without any other feature of carcinoma. In
wo other patients, the angiographic presentation
as similar to that seen in the cases of pancreatic
arcinoma. Pathological vessels were seen in at
east part of the tumor in all 30 cases of pan-
reatic carcinoma. Two carcinomas showed intense
umor blush. Serrated encasement occurred in 61%
f the 30 pancreatic carcinomas, smooth encasement
n 22%, and serpiginous encasement in 17%. The
mallest lesions detected by pancreatic arterio-
raphy were less than 2 cm in diameter; among
hese, one was found in the ampulla, one in the
ead/body region, and two in the tail of the pan-
reas. Since noninvasive imaging techniques are
ow available, angiographic diagnosis of pancreatic
arcinoma is often not required. The new purpose
f angiography in the diagnosis of pancreatic car-
inoma is the demonstration of small and still
urable lesions.

8400 THE PANCREAS AND IMMUNOGLOBULINS. III.
SECRETORY LEVELS OF IMMUNOGLOBULINS G, A,
IN PATIENTS WITH HYPERSECRETORY DISEASE, POST-
IDNEY TRANSPLANTATION AND PANCREATIC CARCINOMA. A
EW DIAGNOSTIC TEST. (Eng.) Soto, J. M.; Aufses,
. H., Jr.; Dreiling, D. A. (Mt. Sinai Sch. Medi-
ine, City Univ. New York, 100th St. and 5th
ve., New York, NY 10029). *Am. J. Gastroenterol.*
8(1):34-37; 1977.

he IgG, IgA, and IgM levels in pancreatic juice
ere investigated in three groups of patients to
etermine the diagnostic value of this parameter.
enal transplant patients (4) on immunosuppres-
ive drugs, patients with hypersecretory dis-
ase (7 with minimal pancreatitis and 7 with
ypersecretory pancreatic dysfunction of varying
tiology), and 9 patients with pancreatic carcin-
ma were tested and compared with 38 normal pa-
ients and 15 patients with chronic pancreatitis.
here were no significant differences between the
ormal controls and either the renal transplant
atients or the patients with hypersecretory dis-
ase. In patients with pancreatic carcinoma, IgA
as absent from pancreatic juice except for high
evels in patients with very early lesions and
rom whom juice was obtained directly from the
uct of Wirsung following secretin stimulation;
he data for IgG levels in these patients showed
catter, but the average level was markedly higher
han in any other group. The IgM level in carcin-
ma patients was not different from that in any
ther group. It is concluded that immunosuppres-
ive therapy does not alter the immunoglobulin
content of pancreatic juice, that hypersecretion does not dilute pancreatic immunoglobulin concentrations, and that the altered immunoglobulin profile in pancreatic carcinoma patients may constitute a new diagnostic test for pancreatic cancer.

PANCREAS

Pancreatitis

8412 STUDY OF THE PRINCIPAL PANCREATIC DUCT BY SONOGRAPHY. (Fre.) Pietri, H.; Palasciano, G.; Aimino, R.; Serafino, X. (Institut J. Paoli I. Calmettes, 232 bd de Sainte Marguerite, F 13273 Marseille Cedex 2, France). *Nouv. Presse Med.* 7(2):113-115; 1978.

A new technique is described for visualizing a dilated main pancreatic duct (Wirsung's canal) by ultrasound. The transducer must be used with a sweep motion in only one direction while positive pressure is exerted on the epigastrium. On a transverse section, the duct appears spindle shaped. It is in the shape of a circle 4 mm to 2 cm in diameter in the center of the pancreas on sagittal section. The method visualized the duct in 4/10 patients with chronic pancreatitis, whereas former methods successfully visualized the duct in 20/140 patients with dilated ducts.

8413 PARENTERAL NUTRITION IN THE TREATMENT OF ACUTE PANCREATITIS: EFFECT ON COMPLICATIONS AND MORTALITY. (Eng.) Goodgame, J. T.; Fischer, J. E. (Natl. Cancer Inst., Natl. Inst. Health, Bethesda, MD 20014). *Ann. Surg.* 186(5):651-658; 1977.

Clinical characteristics of 46 patients with acute pancreatitis treated with total parenteral nutrition (TPN) were examined. The duration of TPN varied from 5 to 90 days, with an average of 28 days. TPN was discontinued after p.o. intake was adequate in 33 of the 46 patients. Five patients were hyperalimented until their death, and TPN was discontinued in two patients when hope for their recovery was lost. TPN was discontinued in six patients because of complications directly related to this treatment modality. Episodes of catheter-related sepsis prompted discontinuation in five patients, while an inability to control rising serum potassium was the reason for discontinuance in the remaining patient. Despite the 15% incidence of acute renal failure, there were only four episodes of metabolic abnormalities that required discontinuation of TPN. Initial glucose intolerance was common (25%), but was usually controlled by temporarily reducing th infusion rate or by incorporating small amounts (10-20 U) of regular insulin to the infusion mixture. There were two episodes of protein intolerance, one occurring in a patient with a portacaval shunt and the other in a patient with persistent bacteremia. Hypocalcemia occurred in seven patients. Twenty-two patients experienced no complications after definitive therapy of their acute attack of pancreatitis, although 18 required surgery. Cardiovascular complications were the most frequent, followed by respiratory insufficiency, renal insufficiency, metabolic abnormalities, surgical complications, and bleeding dyscrasia. The major hyperalimentation related morbidity involved episodes of catheter sepsis, which occurred in 8 of 99 catheterizations. Nine deaths occurred in this series. Twelve of 15 patients who were critically ill with nonfunctioning gastrointestinal tracts survived, which supports the opinion that the maintenance of nutritional integrity in the absence of a completely functional gastrointestinal trac and in the presence of severe illness is essential. It is concluded that TPN should be seen as a method of support and not as a primary therapy in acute pancreatitis.

8414 GLUCAGON IN THE TREATMENT OF ACUTE PANCREATITIS. (Ita.) Quaranta, L.; Segr D.; Balestrino, E.; Beltrutti, D. (Ospedale Civi "S. Croce," Cuneo, Italy). *Gaz. Med. Ital.* 136(369-376; 1977.

A description of acute pancreatitis is given uti izing published accounts, and data on 25 new cas are presented to emphasize the role of glucagon treating this disease. Patients were given 1 mg of glucagon every 6 hr in continuous infusion i physiological solution. Treatment was continue

r 2-3 days after normalization of serum and
ine amylase values. Patients were also given
)00,000 IU Trasylol/day. There was a rapid
crease in amylasemia in all of the patients.
e blood glucose values showed that the patients
lerated the therapy very well. The serum calcium
vels oscillated between 8 and 9 mg%. The re-
lts, when compared with previous studies in
ich patients were not treated with glucagon,
ow that the pharmacological regimen reported in
is paper brings about a more rapid remission of
e acute phase of the disease, presumably by
ocking edema and impeding the development of
crosis and hemorrhage.

15 PROSPECTIVE STUDIES ON THE SIGNIFICANCE OF PROTEINASE INHIBITORS AND GLUCAGON IN
JTE PANCREATITIS.

(Ger.) Kirsch, A.; Werner,
; Heinze, D. (Chirurgische Klinik, Stadtisches
ankenhaus im Friedrichshain, DDR-1017 Berlin,
ninallee 49, E. Germany). *Zentralbl. Chir.* 108
):291-303; 1978.

e therapeutic effectiveness of glucagon and the
oteinase inhibitor Contrykal was studied in a
ndomized series of 403 patients with acute pan-
eatitis. All patients received basic therapy
nsisting of permanent gastric suction, plasma
fusion, and analgesia with procaine. Patients
ceiving Contrykal also received atropine. Mild
ncreatitis was diagnosed in 79 cases, medium-
gree pancreatitis in 198, and severe pancreati-
s in 126. Seventy-five randomly selected pa-
ents were treated with Contrykal (60,000-150,000
while 75 controls received basic therapy only.
ere were 10 recurrences, 1 pseudocyst, and 1
ychosis in the control group, while there were 5
currences, 1 pseudocyst, 2 psychoses, and 1 pan-
eatic abscess in the Contrykal-treated group.
e average duration of plasma infusion was 60.5 hr
thout Contrykal and 77.3 hr with Contrykal.
e average duration of the hospital stay was 12.8
ys without Contrykal and 13.6 days with Contrykal.
venty-five patients received glucagon (10 mg/day
v.) in addition to the basic therapy and 75
ntrols received basic therapy only. In the
ucagon-treated group, six patients developed
currences, four psychoses, three abscesses, and
e a pseudocyst. In the control group, five pa-
ents developed recurrences, three psychoses, two
eudocysts, and one abscess. The average length of
asma infusion was 72.1 hr in the treated pa-
ents versus 65.8 hr in the controls; the average
ngth of the hospital stay was 18.9 days in the
eated group versus 14.7 days in the controls.
e remaining group of 103 patients received basic
erapy only; 2 developed pseudocysts and 2 psy-
oses. The average duration of hospital treat-
nt was 14.7 days, the average duration of in-
sion 67.4 hr. The findings suggest that the re-
lts were best in the groups receiving the basic
erapy only.

16 INTRASPLENIC PANCREATIC PSEUDOCYST COMPLICATING SEVERE ACUTE PANCREATITIS.

(Eng.) Hastings, O. M.; Jain, K. M.; Khademi, M.; Lazaro, E. J. (Martland Hosp., 65 Bergen St., Newark, NH 07107). *Am. J. Gastroenterol.* 69(2):182-186; 1978.

A case of intrasplenic pancreatic pseudocyst complicating severe acute pancreatitis is presented. The patient was a 27-yr-old alcoholic man who presented with a 4-week history of upper abdominal pain, malaise, and dyspnea. The abdomen was distended and tender, and a poorly defined epigastric mass was palpated. A left-sided pleural effusion was present, necessitating thoracocentesis and subsequent thoracostomy. The patient's clinical condition failed to improve with conservative therapy, and exploratory laparotomy was carried out. At celiotomy, a large, thin-walled cyst, involving the distal half of the pancreas and in juxtaposition to the stomach, was encountered. Because of the immaturity of the cyst wall, external drainage was performed. Cyst fluid cultures grew beta hemolytic streptococci. A postoperative upper gastrointestinal series demonstrated extrinsic pressure on the stomach, and a selective celiac arteriogram, carried out 21 days postoperatively, revealed an avascular area of the spleen. At re-exploration 6 weeks after the initial operation, the angiographic avascular area was found to be a cystic mass, which had an amylase content of 733 Conway U. The spleen was enlarged, and splenectomy was performed. Histopathology of the spleen was unremarkable, and the cyst wall showed a nonepithelial lining with chronic inflammatory changes. Early surgical intervention with splenectomy and possibly caudal pancreatectomy is advocated in cases of intrasplenic pancreatic pseudocyst.

8417 ACUTE PANCREATITIS TREATED WITH AND WITHOUT ADDITION OF INSULIN.

(Eng.) Hallberg, D. (Karolinska sjukhuset and Serafimerlasarettet, Stockholm, Sweden). *Acta Chir. Scand.* 143(7/8):451-456; 1977.

Two treatment modalities for acute pancreatitis were compared retrospectively by reviewing 365 case histories from a 5-yr period. One modality involved well-supervised conservative treatment with gastric drainage, fluid and electrolytes given i.v., pain sedatives, and anticholinergic drugs; 165 patients were treated 222 times in this way. The second modality added insulin (20-40 IU/1,000 ml of glucose solution, infused i.v. as needed) to the first regimen; 258 patients were treated 408 times in this way. There were 58 patients treated in both ways at different times; 2 of them died while on treatment without insulin. Among 200 patients treated only once with insulin, 44 were treated during a recurrence (none died) and of the other 156, 5 died. Among 107 patients treated without insulin, 10 died and 9 had recurrences among whom 1 died. Thus, the mortality among the 258 subjects treated with insulin at least once was 1.9%, whereas the mortality among the 165 subjects treated without insulin was 7.9% (if the mortality rates are calculated per hospital admission, they are 1.2% among 408 and 5.9% among 272, resp.). These differences are statistically significant ($p<0.05$). There were no other significant differences between the two groups; age and sex distribution, positive information of gallstone disease or pancreatitis in 0-10 yr after biliary surgery, positive information of alcohol abuse, serum Ca levels, percentage of serious cases, kinds of surgical intervention, or length of hospital stay were the factors examined. The results support a pathogenetic concept for acute pancreatitis that is based on the incorrect activation of cyclic AMP in abdominal organs, leading to enhanced lipolysis, decreased splanchnic blood flow, pain, accumulation of free fatty acids in the splanchnic adipose tissue, hypocalcemia, and fat necrosis in the abdominal adipose tissue. The insulin plus glucose treatment is believed to inhibit or decrease lipolysis and increase splanchnic blood flow and so reverse the postulated series of events that constitute acute pancreatitis.

LIVER AND BILIARY TRACT

38 STUDY OF THE LIVER BY COMPUTERIZED
TOMOGRAPHY. EVALUATION OF ONE YEAR'S
PERIENCE WITH 1,480 INVESTIGATIONS. (Fre.)
teaux, M.; Coenen, H.; Struyven, J.; Marchal, G.;
venne, R.; Jeanmart, L.; *et al.* (Departement de
mographie Computee, Universite Libre de Bruxelles,
rue Heger-Bordet, 1000 Brussels, Belgium). *J.
diol. Electrol. Med. Nucl.* 58(12):765-772; 1977.

critical analysis of the use of computerized
mography (Delta Scanner: Ohio Nuclear) in the
agnosis of liver pathology is presented based on
udy of 1,480 patients. Initially, two studies
re performed, one before and one after i.v. injec-
on of contrast product (100 ml methylglucamine
atrizoate). The tomography without contrast was
ne to avoid masking a hypervascular lesion, but
is situation was not encountered, and only the
ntrast study was done later in the series. The
ecific pathology for 520 patients was hepatomegaly
85, cirrhosis in 50, steatosis in 5, abscess in
, hematoma in 3, ascites in 22, cystic formations
13, biliary cysts in 7, hepatorenal polycystosis
2, primary tumor in 16, metastatic infiltrations
107, regional cancer infiltration of the liver in
hepatic artery aneurysm in 1, and gallbladder dis-
se (lithiasis) in 26. There were 12 false-positive
sults, attributed to images of feeble density.
the 50 false-negative results, 28 were metastases
small size and 16 were of diffuse pathology, par-
cularly lymphomatosis. Circumscribed pathology,
ether of tumoral, infectious, or traumatic origin,
s readily visualized. Diffuse lesions, on the other
nd, with the exception of hepatic steatosis, were
fficult to visualize by computerized tomography.

39 INVESTIGATIONS ON ALBUMIN EXCRETION OF
THE LIVER INTO THE BILE. II. DISC ELEC-
ROPHEROGRAMS OF DUODENAL BILE. (Ger.) Rogos, R.;
etzold, H. (Kreiskrankenhaus, Leipziger Str. 55,
DDR-74 Altenburg, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 38(1):27-32; 1978.

Forty-nine samples of A-bile, 45 samples of B-bile, and 60 samples of C-bile from patients with chronic active hepatitis, liver cirrhosis, atrophic gastritis, cholangitis, acute hepatitis, and irritable colon were studied by disc electrophoresis. Protein fractions that migrated to the cathode were found to be predominant. A typical albumin peak was found in 5/60 C-biles only. These findings show a substantial difference from the electropherogram of T-drain bile. The *in vitro* decomposition of albumin from T-drain bile by trypsin suggests that upon entry into the duodenum, the albumin is rapidly and completely decomposed by the excess amount of proteases present and that its decomposition is faster than that of globulins. Since the albumin metabolites are resorbed, this albumin is part of the endogenous protein reserve. The electrophoretic pattern of the duodenal bile proteins is superimposed by that of protein metabolites, and therefore it was not a reproducible diagnostic tool despite the use of a protease inhibitor in the preparation.

8440 TOTAL SERUM BILE SALTS IN LIVER DISEASES. (Ita.) Annoni, G.; Barbi, G.; Del Ninno, E.; Ideo, G. (Istituto di Clinica Medica III dell' Universita di Milano, Milano, Italy). *Minerva Dietol Gastroenterol.* 23(2):59-65; 1977.

The usefulness of total serum bile salts as an index of liver disease was determined in 117 patients with hepatopathy and possible correlations between this measurement and other common indices of hepatic function were sought. Twelve patients had acute hepatitis, 20 chronic hepatitis, 35 chronic active hepatitis, 35 chronic active hepatitis with cirrhosis, and 15 inactive cirrhosis. All five groups of patients had significantly raised average serum levels of total serum bile salts in comparison with healthy individuals ($p<0.001$). The coefficient of correlation between bile salt levels and BSP level was highly significant: $p<0.05$ for chronic hepatitis and $p<0.001$ for chronic active hepatitis with or without cirrhosis and for inactive cirrhosis. The results of a meal test showed that the patients with hepatopathy had a notably augmented level of bile salts. The results show that total serum bile salts represent a highly sensitive index of cholestasis and that the meal test best demonstrates the presence of hepatopathy.

8441 DETERMINATION OF HUMAN LIVER CYTOCHROME P-450 BY A MICROMETHOD USING ELECTRON PARAMAGNETIC RESONANCE: STUDY OF 141 LIVER BIOPSIES.

(Fre.) Gabrielle, L.; Leterrier, F.; Molinie, C.; Essioux, H.; Cristau, P.; Laverdant, C. (Centre de Recherches du Service de Sante des Armees, 1 bis, rue du Lieutenant-Raoul-Batany, F92141 Clamart, France). *Gastroenterol. Clin. Biol.* 1(10):775-782; 1977.

A micromethod is described for the measurement of the level of cytochrome P-450 in human liver needle biopsies, and the results of such determination in 141 specimens are given. The specimens were obtained from 33 patients with histologically normal livers, 31 patients with bilharziosis but functionally normal livers, 19 with viral hepatitis with symptoms of at least 3 months duration, 3 with extrahepatic cholestasis, 38 with alcohol-induced fatty degeneration of the liver, and 15 with cirrhosis confirmed by histological examination. The method measures the electron spin resonance (ESR) of whole liver samples (3-20 mg) frozen in liquid nitrogen and the amplitude of the P-450 $g=2.27$ line; it was first tested on liver samples from Sprague-Dawley rats. Calibration of the ESR values for cytochrome P-450 in rat liver was established by comparing the observed values with those obtained by absorption spectrophotometry. The normal value for P-450 level established for patients without liver pathology was 43 ± 20 nmol/g liver. Patients with viral hepatitis with signs of recovery had values of 39.3 ± 21 nmol/g. Patients with persistant or active viral hepatitis had markedly decreased cytochrome P-450 values (4.3 ± 5.7 nmol/g). The patients with fatty liver degeneration had values of 43.9 ± 22.7 nmol/g, whereas the patients with alcoholic cirrhosis had values of 14.7 ± 17.4 nmol/g. The three patients with extrahepatic cholestasis had values of 73.8, 33.3, and 20.5 nmol/g, resp. This method permits determination of the liver enzyme cytochrome P-450 using very small liver samples (3-5 mg) that can be obtained by needle biopsy.

8442 BILE LYSOSOMAL ENZYMES; CHARACTERISTICS AND PATHOLOGICAL SIGNIFICANCE FOR VARIOUS HEPATOBILIARY DISORDERS.

(Eng.) Toyoda, S.; Eto, Y.; Aoki, K. (Tokyo Jikei Univ. Sch. Medicine, Nishishinbashi, Minato-ku, Tokyo, Japan). *Clin. Chim. Acta* 79(2):291-298; 1977.

The presence of several glycosidases in human bile was established in 25 patients, and their pathological significance in various hepatobiliary disorders was studied. The activities of β-galactosidase, β-glucosidase, and *N*-acetyl-β-glucosaminidase were demonstrated in the bile of seven normal subjects, using 4-methylumbelliferyl derivatives as substrates. The enzyme activities were increased 60- to 180-fold after the exclusion of bile salts and other small molecular compounds by Sephadex G-50 gel filtration. In patients with cholelithiasis, the mean activities of β-galactosidase and *N*-acetyl-β-glucosaminidase were significantly decreased ($p<0.01$). These activities were also significantly decreased in patients with acute hepatitis and liver cirrhosis ($p<0.01$). β-Galactosidase activity was within normal limits in one patient with gallbladder cancer, and that of β-glucosidase was near the upper limit in patients with bacterial cholangitis. Isoelectric focusing patterns of biliary glycosidases were similar for specimens from patients with hepatobiliary disorders as compared with normal individuals. This investigation presents firm evidence that lysosomal enzyme activities are present in bile.

8443 CHRONIC PATHOLOGY OF THE LIVER IN ITALY. COOPERATIVE RETROSPECTIVE STUDY.

(Ita.) Ascione, A.; Barcellona, R.; Benini, G.; Budillon, G.; Candalaresi, M. T.; Cataldi, V.; *et al.* (As- sociazione Italiana per lo Studio del Fegato, Naples, Italy). *Recent. Prog. Med. (Roma)* 63(5): 447-470; 1977.

The etiology, nosology, and socio-environmental f tors of chronic hepatopathies were studied retrospectively and compared to the incidence and loca tion of chronic hepatopathies in four regions of Italy (North, Central, South, and Sicily). Data were collected from 18 hospitals and university clinics on 5,055 cases of chronic hepatopathy observed in 1972-1974. The distribution of the cases was 2,522, 472, 1,614, and 447 in each of the 4 regions, resp. As percentages of the total cases in each region, resp., the incidence of cirrhosis (all types) was 58.3, 67.1, 57.3, and 71.9%; of primary carcinoma was 3.2, 4.2, 3.8, and 10%; of chronic aggressive hepatitis was 6.2, 8.0, 19.1, and 8.5%; of chronic persistent hepatitis was 4.1, 6.1, 5.9, and 3.5%; of noncirrhoti pathology due to alcohol was 21.5, 3.8, 3.1, and 0.7%; and of noncirrhotic pathology secondary to biliopathy was 1.7, 4.6, 5.4, and 0.7%. The differences among all four regions were statisticall significant ($p<0.05$) for alcoholic cirrhosis (No Central>South>Sicily) and for cryptogenic cirrho (Sicily>South>Central>North). Posthepatic cirrh and chronic aggressive hepatitis were significan more prevalent in the South ($p<0.05$), and hepato carcinoma was more prevalent in Sicily ($p<0.05$). Noncirrhotic pathology due to alcohol was significantly more prevalent in the North than in the Central or South regions ($p<0.05$) and signif icantly more prevalent in the latter two regions than in Sicily ($p<0.05$). When the incidences of various types of cirrhosis are compared with the total number of cases of cirrhosis, significant

($p<0.05$) regional differences were found for cryptogenic cirrhosis (Sicily>South>Central>North), for alcoholic cirrhosis (North>Central>South>Sicily), posthepatic cirrhosis (South>all other regions), and siderochromatosis (North>South, no cases in the other regions). Significant regional differences were found in the distribution of alcoholics and habitual drinkers versus moderate consumers and abstainers ($p<0.05$, North>Central>South>Sicily), in the percentage of female alcoholics (13.1% in the North, $p<0.05$), the percentage of female habitual drinkers (31.4% in the North and 32.2% in the central area, $p<0.01$), in the male/female ratio of the incidence of alcoholic cirrhosis (20.0% in Sicily, $p<0.01$), and in the incidence of primary carcinoma (5.3% in Sicily, $p<0.05$). Patients with hypocaloric diets had greater incidences of chronic hepatopathy than did those with hypercaloric diets. A greater number of people from the lower economic group had cirrhosis due to alcohol, idiopathic siderochromatosis, and noncirrhotic pathology due to alcohol than did those from the middle and upper income groups. Manual workers had a higher incidence of all types of chronic hepatopathy compared with persons in other types of occupations ($p<0.01$). This study is the first overview of the principal problems of chronic liver pathology with respect to geographic regions and of the role of alcohol in this pathology.

8444 LIVER COLLAGEN. (Fre.) Frey, J.; Bayle, J. J. (U.E.R. de Medecine, 30 rue Ferdinand Gambon, F 42100 Saint-Etienne, France). *Lyon Med.* 239(2):87-93; 1978.

Pathological conditions of the liver characterized by fibrosis are reviewed and discussed on the basis of current knowledge of normal collagen structure and metabolism. Three pathogenic mechanisms are considered: (1) modification of gene expression that determines the respective importance of type I and type II collagen, (2) increase in the activity of the enzymes of post-translational biosynthesis, and (3) decrease in collagenolytic activity. Methods of investigating alterations in collagen metabolism that may lead to diagnosis of liver pathology are discussed. These methods measure enzymes or metabolites in the blood and urine that reflect alterations in synthesis or degradation of collagen. The excretion of enzymes involved in collagen biosynthesis such as procollagen-prolylhydroxylase may be increased in hepatomas, and some authors have found an increase in blood and urine hydroxyproline, a collagen component, associated with the hepatic cirrhosis of chronic alcoholism.

8445 ALPHA-FETOPROTEIN: PART ONE OF GENERAL REVIEW. (Fre.) Delpre, G.; Gilat, T. (Hopital Beilinson, Petah Tikva, Israel). *Gastroenterol. Clin. Biol.* 2(1):87-106; 1978.

The literature on various techniques of measuring alpha-fetoprotein (AFP) in different areas of the body (serum, urine, cerebrospinal fluid, saliva) and the pathological conditions associated with high levels of serum AFP are reviewed. One table gives the limits of sensitivity of detection of AFP by 18 different methods, and another table gives the upper, median, and average values of serum AFP in the healthy subject as determined by radioimmunoassay and enzymatic immunoassay. The levels of AFP in the serum associated with primary and metastatic carcinoma of the liver are discussed; variations in AFP have been found in these patients according to age, sex, race, histological type of carcinoma, presence or absence of cirrhosis, size of tumor, and geographical locale of study. AFP levels found in other malignant tumors in adults (including teratoblastomas, embryonic tumors, and gonadal tumors) are discussed with respect to their diagnostic value. Literature on pathogenesis of elevated AFP levels in hepatic and other tumors is reviewed.

8446 GENERAL REVIEW: ALPHA-FETOPROTEIN. PART II. (Fre.) Delpre, G.; Gilat, T. (Beilinson Hosp., Petah Tikva, Israel). *Gastroenterol. Clin. Biol.* 2(2):193-214; 1978.

The literature concerning the involvement of alpha fetoprotein (AFP) in nonmalignant liver diseases (fulminant, acute, and chronic), in hepatocellular carcinoma (HCC) and its diagnosis, in diseases of children and neonates (malignant tumors, liver diseases, and metabolic and genetic diseases), in pregnancy, and in immunity is reviewed. In variou nonneoplastic liver diseases such as cirrhosis and hepatitis, the levels of serum AFP have been found to be useful indicators of the extent, progression, and reversal of the process. A definite relationship appears to exist between serum AFP and HBsAg levels i acute and chronic liver diseases that progress to HCC, although there is some controversy about this association and its application in differential diagnosis. There is also some controversy about the usefulness of markedly elevated serum AFP levels as an early indicator of HCC; the response of these AFP levels to chemotherapy and radiotherapy for HCC may be useful in indicating the efficacy of the therapy. In pediatric and neonatal liver diseases there seems to be a gap between the level of serum AFP in normal individuals compared with that in patients as in adults, but the serum AFP level does not aid the differential diagnosis of HCC from hepatitis as it does in adults. Serum AFP levels have been reported to be elevated in children and neonates with primary liver cancer, teratoma, acute viral hepatitis, congenital biliary atresia, in some chronic hepatopathies (such as infantile cirrhosis), and in some genetic and metabolic diseases, but the interpretation of serum AFP levels in these patients must be approached with caution and may depend on the age of the subject. The diagnostic significance of AFP levels in normal and abnormal pregnancies is discussed; the variation of AFP levels in the fetus, in maternal blood, and in amniotic fluid has a normal course, and deviations from these levels may indicate pathologies. AFP in immunity is discussed with respect to individual tolerance to autogenous AFP, ways in which this tolerance can be disrupted, and the role of AFP in immunosuppression.

8447 ALPHA-FETOPROTEIN IN THE DIAGNOSIS OF MALIGNANT NEOPLASMS.

(Ita.) Burke, P.; Bianco, L. (Istituto di Clinica Medica dell' Universita di Torino, Torino, Italy). *Minerva Dietol. Gastroenterol.* 23(2):91-94; 1977.

The incidence of alpha-fetoprotein (AFP) in 42 patients (21 patients had liver cirrhosis, 1 had acute viral hepatitis, 2 had chronic hepatitis, and 18 had various types of cancer) was determined by radial immunodiffusion and a modification of cross-over electrophoresis. Four of the patients had AFP in their sera (2 had primary hepatomas, 1 had metastasis of testicular teratocarcinoma, and 1 had hepatic cirrhosis). The quantitative values for AFP were 310 mg% ml and 230 mg% ml in the cases of primary hepatoma, 1 mg% ml in the case of testicular teratocarcinoma, and >0.7 μg/ml but <1 mg% ml in the case of hepatic cirrhosis. The results show that AFP serum levels are notably greater in cases of hepatoma than in other hepatopathy.

8448 A STUDY OF HEPATOCELLULAR CARCINOMA AMONG JAPANESE FROM THE POINT OF VIEW OF MORPHO-DEVELOPMENTAL PATHOLOGY--GROSS ANATOMICAL TYPES CLASSIFIED IN ITS RELATION TO CAPSULE FORMATION.

(Eng.) Nakashima, T.; Sakamoto, K. (Kurume Univ. Sch. Medicine, Kurume, 830, Japan). *Kurume Med. J.* 24(Suppl.)S43-S62; 1977.

One hundred seven necropsies and seven surgically resected livers were studied to develop a system for classifying hepatocellular carcinoma (HCC) with respect to capsule formation. In Japan, encapsulated HCC is frequent (60-70% of the cases), while elsewhere it is infrequent (e.g., 3.6% of the cases in Los Angeles). The classification parameters used were changes in the parenchyma and the growth pattern of the tumor. When classified by changes in the parenchyma, type A tumors are HCC unaccompanied by cirrhosis, and type B tumors are HCC accompanied by cirrhosis. Small HCC's were assigned to a separate class (type C) regardless of the presence or absence of cirrhosis, but in all 13 cases studied, advanced cirrhosis was present. Cirrhosis was present in 84/107 cases, hepatitis B surface antigen (HBsAg) was positive in 47.6% of the cases, and the overall male:female ratio was 6:1. Among type A patients, HBsAg was usually negative, and the sex ratio was 2.3:1. When classified by growth patterns, type I tumors were the infiltrating type (tumor cells infiltrating into the sinusoids and perisinusoidal areas of the adjacent liver parenchyma), type II tumors were the expanding type (tumor tissue forming a mass that expands as the tumor grows, compressing neighboring liver parenchyma that atrophies and disappears and a connective tissue capsule often forming at the boundary--encapsulated type), type III tumors were the multiple type (HCC metastasizing hematogenously at certain stages of growth, forming multiple separate lesions in the liver parenchyma), and type IV tumors were encapsulated HCC having additional infiltrative lesions or encapsulated HCC continuous with infiltrative lesions suggesting a transition. In the present classification, sclerosing HCC was included in the infiltrative type. Other systematic studies of HCC in Japan are described. T present classification was designed to meet the clinical demand for early diagnosis and early surgery in the treatment of HCC.

8449 ULTRASTRUCTURE OF THE LIVER IN HUMAN AMYLOIDOSIS.

(Eng.) Eguchi, T.; Fukud K.; Okugawa, N.; Tanikawa, K.; Kimura, N. (Kurume Univ. Sch. Medicine, Kurume, 830, Japan). *Kurume Med. J.* 24(4):229-235; 1977.

Liver biopsy specimens from two patients with primary amyloidosis were examined histologically and ultrastructurally. Histological examination revealed that amyloid deposits around vessels in the portal area were minimal in the first patient but extensive in the second. The basic lobular architecture was destroyed as a result of the amyloid deposits in the latter patient. Electron microscopy in the first patient showed minimal development of amyloid fibrils in the space of Di Fine amyloid fibrils in this area were arranged in parallel and measured approximately 50-125 A in width. Amyloid material was limited to the portal area. The cytoplasm of the hepatocytes a the bile canaliculus appeared normal. Extracellular spindle-shaped amyloid bundles were seen within invaginations of the plasma membrane of reticuloendothelial cells. Filamentous structure were also noted within the cell, although there was no continuity between extra- and intracellula filaments. In the second patient, hepatocytes appeared to be reduced in proportion to the exte of amyloid deposition. However, the lobular architecture remained normal in some areas, and in these areas a moderate degree of amyloid depo tion was noted in the space of Disse. The amylo deposit within the space of Disse seemed to spre toward the hepatocyte with resultant constrictio of the hepatocyte. No amyloid deposits were not within the hepatocyte, although the endoplasmic reticulum was vesiculated, and other organelles showed moderate changes. Hepatocytes disappeare in the vicinity of massive amyloid deposits. Ir regularly shaped reticuloendothelial cells with large nuclei were often found, and dense amyloid deposits were frequently observed between the cytoplasmic processes of these cells. There appeared to be continuity between extra- and intra cellular amyloid filaments. It appears that reticuloendothelial cells play an important role in amyloid production.

8450 LIVER DISEASE IN HOMOZYGOUS α_1-ANTI-TRYPSIN DEFICIENCY.

(Ger.) Karitzky, D.; Lesch, R.; Goedde, H. W.; Witt, I.; Boehm, N Beckmann, R.; *et al.* (Universitats-Kinderklinik, Mathildenstr. 1, 7800 Freiburg, W. Germany). *Dt Med. Wochenschr.* 103(4):161-166; 1978.

ntile liver disease was diagnosed in 5 of 12
dren with homozygous α_1-antitrypsin deficiency
-type Z). The course of the disease in these
ents was extremely variable. One of the five
ents died from liver cirrhosis at the age of
r. The clinical, biochemical, and (in 2 cases)
histological findings in the other four pa-
ts became normal over a follow-up period of
yr. The findings indicate that α_1-antitrypsin
ciency, even when associated with liver dis-
, need not have an unfavorable prognosis.

INTRAHEPATIC CYSTIC BILE DUCT DILATATIONS
AND STONE FORMATION: A NEW CASE OF CAR-
S DISEASE. (Eng.) Mathias, K.; Waldman, D.;
eler, G.; Kauffmann, G. (Universitats-Kliniken,
stetterstr. 55, D-7800, Freiburg, W. Germany).
Hepatogastroenterol. (Stuttg.) 25(1):30-34;
.

pathology, clinical signs, diagnosis, differ-
al diagnosis, therapy, and prognosis of Caroli's
ase are briefly reviewed, and a new case of the
ase is reported. Caroli's disease is a rare
lial anomaly with circumscribed saccular dila-
ons of enlarged intrahepatic bile ducts coated
egular or pseudopapillomatous epithelium and
be combined with additional malformations of
extrahepatic biliary tract as well as with
llary sponge kidney. Infection and stone
ation are frequent complications. Most pa-
ts complain of upper abdominal pain caused by
angitis and gallstones; liver abscesses and
icemia may also occur. Patients may therefore
ent with colic, fever, and icterus. Extra-
tic lithiasis occurs frequently. Diagnosis by
cholangiography (demonstrating the opacifi-
on of ectatic bile duct segments) easily over-
s Caroli's disease because the associated
ons are more remarkable; it is improved by
graphy. Other diagnostic methods include
a- or postoperative cholangiography, barium
ies, endoscopic retrograde cholangiography,
percutaneous transhepatic cholangiography.
ratory examinations are noncontributory, lap-
copy and laparotomy are unreliable, and liver
sy is contraindicated. Differentiation be-
n Caroli's disease and biliary cyst formation,
ructive cholangitis, biliary obstruction, poly-
ic liver disease, and solitary hepatic cysts
resented. Surgery is indicated if the disease
imited to one lobe (which should be resected)
f the disease is diffuse (papillotomy or
odigestive anastomosis may be useful). Gall-
e dissolution and prevention and antibiotics
important in symptomatic therapy. Caroli's
ase is often life-shortening; patients die
epticemia, cholangitis, liver abscess, chol-
ocellular carcinoma, relapsing cholangitis,
pancreatitis. A 31-yr-old woman with a sev-
-year history of upper abdominal pain, colic,
relapsing pancreatitis underwent cholecys-
omy and transduodenal papillotomy for cho-
iolithiasis, intrahepatic bile duct ectasia,
papillary sclerosis; also, all stones were
ved from the choledochal duct. Despite antibiotic therapy for cholangitis and chenodeoxycholic acid therapy (both by infusion through the T-drain and p.o.), cystic dilatations of the bile ducts and intrahepatic gallstones persist.

8452 INTRAHEPATIC PIGMENT STONES: AN ASIAN DISEASE DIAGNOSED WITH RETROGRADE CHOLANGIOGRAPHY. (Eng.) Johnson, L. F.; Walta, D. C. (Walter Reed Army Medical Center, Box 431, Washington, DC 20012). *Am. J. Dig. Dis.* 23(Suppl. 5):13s-18s; 1978.

The case of a patient with intrahepatic biliary pigment stones diagnosed by endoscopic retrograde cholangiography (ERC) is presented, and the authors' experience with this disease is reviewed. The patient, a 29-yr-old Oriental man, presented with recurrent pruritus and jaundice. At the first admission, the SGOT level was 217 IU, and the alkaline phosphatase level was 19.4 Bodansky U. A p.o. cholecystogram showed poor opacification and, at peritoneoscopy, hepatomegaly was noted, with a normal-appearing gallbladder. Liver biopsy showed pericentral cholestasis with triaditis and bridging of portal areas. An i.v. cholangiogram, performed after the resolution of jaundice, revealed normal common and cystic ducts. Hepatic biopsy was complicated by bleeding and prompted surgical intervention, which confirmed the large noncirrhotic liver, normal gallbladder, and normal common bile duct. The biopsy showed bile stasis, portal fibrosis, and mixed inflammatory infiltrate. Two years later, the patient's symptoms recurred, and biopsy revealed features compatible with extrahepatic obstruction. ERC at this time showed an obstruction proximal to the common hepatic duct bifurcation. Intrahepatic biliary radicles did not fill. Ten days later, a percutaneous hepatic cholangiogram failed to opacify any biliary duct despite a demonstrated obstruction on the retrograde cholangiogram. An operative cholangiogram showed a marked impaction of the intrahepatic biliary radicles with fine pigment stones and biliary sludge. A T-tube was placed in the common bile duct, and the patient subsequently received choleretic therapy with phenobarbital and Decholin. Jaundice disappeared, and the serum bile salt concentration dropped to 2.5 mg/100 ml. Fourteen months after the start of choleretic therapy, the biliary radicles were cleared by constant irrigation with a saline-heparin solution. The patient has been asymptomatic on choleretic therapy, although the serum bile salt level increased to 30 mg/100 ml after closing the T-tube tract. In the authors' experience, gallbladder, cystic, and common duct opacification at ERC without intrahepatic filling in the prone, head-down position denotes disease of the intrahepatic biliary radicles.

8453 A COMPUTER SIMULATION STUDY RELATING TO THE TREATMENT OF FULMINANT HEPATIC FAILURE BY HEMOPERFUSION. (Eng.) Berk, P. D. (Liver Unit, DDB:NIAMDD, Bldg. 10, Rm. 4D-52, Natl. Inst. Health, Bethesda, MD 20014). *Proc. Soc. Exp. Biol. Med.* 155(4):535-539; 1977.

Computer simulation techniques were used to investigate what schedule of charcoal hemoperfusion might more rapidly deplete the apparently critical slowly-exchanging extravascular pool of "toxin," which has been hypothesized to accumulate in fulminant hepatic failure and result in liver coma. In contrast to the hypothetical toxin, the internal kinetics of unconjugated bilirubin have been extensively studied, as has its rate of clearance from blood during hemoperfusion with an albumin-agarose "artificial liver" device. In addition, unconjugated bilirubin has an extrahepatic, extravascular pool that exchanges slowly with plasma at a rate not inconsistent with that which must also be obtained for the hypothetical toxin of fulminant hepatic failure. Accordingly, the effects of various albumin-agarose hemoperfusion treatment schedules on the rate of depletion of the extrahepatic extravascular pool of unconjugated albumin were studied. The extrahepatic, extravascular bilirubin pool in an 18-yr-old woman with type I Crigler-Najjar syndrome decreased by only 15% by the end of a 4-hr hemoperfusion period. Bilirubin content continued to fall after the completion of the perfusion; a nadir of 60% of baseline was reached at approximately 24 hr after initiation of the procedure, consistent with the time course of arousal of comatose patients with fulminant hepatic failure after charcoal hemoperfusion therapy. Analysis of the computer-simulated effects of four different treatment schedules (4 hr/day; 12 hr, then 4 hr/day; 24 hr, then 4 hr/day; and continuous) during a 5-day period showed that continuous hemoperfusion was the most efficient, reducing the plasma unconjugated bilirubin concentration to 1.2 mg% and the extrahepatic, extravascular bilirubin pool to values within the normal range by 24 hr. The usually employed 4-hr regimen did not achieve plasma bilirubin values consistently under 6 mg%, and did not bring the extravascular pool within the normal range until after the fourth treatment. Initial perfusions of either 12 or 24 hr, followed by maintenance treatments of 4 hr/day would achieve normalization of the extrahepatic, extravascular pool within 28 and 24 hr, resp., of initiating treatment. Alternatively, two perfusions of 6 hr each, at the start of treatment and at 12 hr would result in normalization of the extravascular pool by 30 hr. The results suggest that albumin-agarose hemoperfusion could reduce the plasma unconjugated bilirubin concentration substantially and the extrahepatic, extravascular bilirubin pool size to normal in patients with type I Crigler-Najjar syndrome. These results are dependent upon both the efficiency of the device and on the treatment schedule.

8454 HEPATITIS B SURFACE ANTIGEN AND α-FETOPROTEIN IN PATIENTS WITH HEPATOCELLULAR CARCINOMA [Letter to Editor]. (Eng.) Chen, D. S.; Sung, J. L.; Kubo, Y.; Okuda, K. (Coll. Medicine, Natl. Taiwan Univ., Taipei, Taiwan, 100, Republic of China). *Gastroenterology* 74(1):163-165; 1978.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

475 PHYSIOLOGIC JAUNDICE OF THE NEWBORN: RELATION TO MATERNAL SERUM AND AMNIOTIC
LUID ALPHA-FETOPROTEIN. (Eng.) Goldstein, A.
.; Farrell, R. C. (Dept. Obstetrics and Gynecology,
niv. California, Irvine, CA 92717). *Obstet.*
ynecol. 51(3):315-317; 1978.

he relationship between physiologic jaundice of
he newborn and elevated levels of maternal serum
nd amniotic fluid alpha-fetoprotein was studied.
ighty-seven paired serum and amniotic fluid specimens taken between 37 and 41 weeks of pregnancy were evaluated. There was an excellent correlation between increased levels of maternal serum and amniotic fluid alpha-fetoprotein and physiologic indirect neonatal hyperbilirubinemia. The maternal serum alpha-fetoprotein levels at 37, 38, 39, 40, and 41 weeks were 384 ± 22, 324 ± 19, 310 ± 23, 272 ± 18, and 253 ± 12 ng/ml, resp., in cases where the neonatal serum bilirubin level was less than 7 mg/100 ml, whereas the values were 451 ± 26, 415 ± 22, 403 ± 16, 387 ± 19, and 344 ± 28 ng/ml in

cases where the neonatal bilirubin level was over 7 ng/100 ml. The amniotic fluid alpha-fetoprotein levels were 394 ± 32, 327 ± 29, 277 ± 26, 271 ± 18, and 258 ± 17 ng/ml in cases in which the bilirubin level was less than 7 ng/100 ml, whereas the levels were 692 ± 16, 681 ± 24, 630 ± 12, 586 ± 14, and 559 ± 17 ng/ml in cases of hyperbilirubinemia. The alpha-fetoprotein assay might be used as an index of fetal liver maturity when considering elective cesarean section or induction.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

8476 ANGIOGRAPHIC ABNORMALITIES AFTER PUNCH BIOPSY OF THE LIVER. (Fre.) Cremniter, D.; Chatel, A.; Bigot, J. M.; Lacombe, P.; Helenon, C. (Hopital Tenon, 4, rue de la Chine, 75970 Paris Cedex 20, France). *J. Radiol. Electrol. Med. Nucl.* 59(1):33-38; 1978.

Vascular abnormalities that developed in nine patients after puncture biopsies of the liver and in one patient after pleural biopsy were detected by angiography. An arterioportal fistula was the abnormality observed in seven patients; the fistula was usually small and disappeared spontaneously. Most often, these fistulas were found accidentally when patients underwent angiography for symptoms related to other pathology. Two patients had hematomas, one of which was associated with an arterioportal fistula. The patient who had a pleural puncture developed a false aneurysm of the distal branch of the hepatic artery and peritoneal hemorrhage. When this patient underwent surgery, a tear in the liver was found that was attributed to the pleural puncture biopsy. Arterioportal fistulas are observed in 60% of patients who undergo angiographic studies within 1 week of liver biopsy. They are rarely serious since they heal rapidly and spontaneously.

8477 DRUG-INDUCED HEPATIC DAMAGE. (Ger.) Keller, J. (Medizinische Universitatsklinik, Hugstetter Strasse 55, 7800 Freiburg, W. Germany). *Therapiewoche* 28(5):762-778, *passim*; 1978.

A review of drug-induced hepatic damage is presented. Drug-induced hepatic damage may be classified according to its clinical features, the histology of the damaged liver tissue, or the mechanism causing the damage. Drugs causing a predictable reaction include cytotoxic drugs with direct hepatotoxicity such as carbon tetrachloride. Drugs causing indirect hepatotoxicity may be cytotoxic or cholestatic, such as tetracycline, methotrexate, *Amanita phalloides*, anabolics, and contraceptives. Drugs that cause unpredictable damage are those that provoke allergic reactions, hyperergy, or metabolic disturbances; some examples are halothane, oxyphenisatin, chlorpromazine, and isonicotinolyhydrazide (INH). Reactions provoked by substances causing predictable damage are characterized by a brief interval between exposure and manifestation of hepatic damage, clear dose-dependence, experimental reproducibility, and nearly universal reaction by exposed persons. Reactions to drugs causing unpredictable damage are generally not dose-dependent and cause allergic hepatic damage or metabolic damage. Diagnostic characteristics of both types are given. A few drugs worthy of special note have been selected for comment; their use and capability for causing liver damage are explained. Among thes are halothane, paracetamol, INH, alpha-methyldopa, i.v. tetracycline, oral contraceptives, chlorpromazine, *N*-propyl ajmalin and derivatives, aprinidine azathioprine, methotrexate, and oxyphenisatin.

8478 A MORPHOLOGIC STUDY OF UNEXPLAINED HEPATITIS FOLLOWING HALOTHANE ANESTHESIA. (Eng.) Wills, E. J.; Walton, B. (Royal Prince Alfred Hosp., Missenden Rd., Camperdown, New South Wales 2050, Australia). *Am. J. Pathol.* 91(1):11-32; 1978.

Liver biopsy specimens from 16 patients who developed hepatitis following halothane anesthesia were examined histologically and ultrastructurally to determine whether the liver morphology could aid in the differential diagnosis between halothane hepatitis and acute viral hepatitis. Ten cases were fatal, although only seven patients died in hepatic failure. Necrosis was not in general disproportionately sever compared with the clinical and biochemical condition of these patients, in contrast with the observations of previous cases of halothane hepatiti However, two patients with clinically equivocal hepatitis had definite morphologic evidence of hepatic inflammation and necrosis. Necrosis tende to be spotty, but in subjects who died rapidly, confluent necrosis was more clearly delineated. Fatty infiltration was unimpressive. Large numbers of eosinophils were seen in two cases. Cholestasis was too varied in degree and localization to be of diagnostic value. Bile ducts were frequently infiltrated with neutrophils and there was often accompanying erosion of the

renchymal limiting plate by inflammatory
lls. Increased portal tract connective
ssue was sometimes as apparent as early
12 days after the onset of jaundice. Light
croscopy of biopsy specimens from three pa-
ents who died from unrelated conditions
en their liver disease was clinically improving
owed a mode of resolution similar to that
viral hepatitis. Bile pigment was seen
trastructurally in the parenchymal cells
th the usual attendant canalicular changes
jaundiced patients. Autophagic activity
hepatocytes and Kupffer cell abnormali-
es were present in some cases. Dilated rough
doplasmic reticulum was observed in most cases
d was the most conspicuous feature in specimens
tained within 14 days of the onset of jaundice.
all defects in the mitochondrial membrane were
served in one patient, and variations in mito-
ondrial size and shape, abnormalities of their
istae, and crystalline inclusions were striking
only one case. Thus, the results do not sup-
rt the contention that the mitochondria are
e most severely affected organelles in halothane
patitis. Since lipid vacuolation and a pre-
minantly centrilobular distribution of necrosis
e not classically described in fatal viral hepa-
tis, the presence of these features in some of
e present fatal cases was of some diagnostic
terest. In general, however, the light and elec-
on microscopic features in patients with unex-
ained postoperative hepatitis have little diag-
stic value.

79 HALOTHANE AND ANTITUBERCULOUS DRUGS--A HEPATOTOXIC COMBINATION? (Ger.) Schmidt-
lcke, H. A.; Wolfert, W.; Grundmann, E. (St.-
anziskus-Hospital Munster, Hohenzollernring 72,
4400 Munster, W. Germany). *Z. Gastroenterol.*
(8):504-511; 1977.

o women who were being treated with isoniazid
00 mg/day) and rifampicin (600 mg/day) or etham-
tol (1,200 mg/day) for tuberculous arachnoiditis
the optic chiasm and lung tuberculosis, resp., de-
loped toxic liver damage a few days following halo-
ane anesthesia for corneal transplantation and
r the treatment of an abscess of a cholecystectomy scar, resp. Both patients had normal liver function before the surgery. Jaundice, pathologically increased serum ammonia, bilirubin, and SGOT levels, and grade III hepatic encephalopathy with somnolence, disorientation, and amnesia were observed. Australia antigen was not found. One patient had undergone halothane anesthesia before tuberculostatic treatment without any complication. Liver biopsy revealed alterations (focal or centrilobular/intermedial liver cell necrosis) compatible with drug hepatitis. The findings did not resemble, however, typical isoniazid hepatitis or typical halothane hepatitis, which suggests the occurrence here of combined toxic effects of halothane and isoniazid on the liver. Complete remission was achieved in both cases in 10-28 days by low-protein diet and lactulose treatment. The absence of literature data concerning an increased incidence of hepatotoxic complications due to the simultaneous use of isoniazid and halothane suggests the possibility of a particular predisposition to this phenomenon in these patients.

Acute Viral Hepatitis

82 RECENT FINDINGS ABOUT THE EPIDEMIOLOGY OF VIRAL HEPATITIS. (Ger.) Baumgarten, R.;
ngler, J. D. (Stadtisches Krankenhaus Prenzlauer
rg, Nordmarkstrasse 15, DDR-1055 Berlin, E. Ger-
ny). *Z. Gesamte Inn. Med.* 32(22):627-630; 1977.

brief review of the present state of knowledge
garding the infectivity and transmission of viral
patitis, sterilization and disinfection to protect
ainst it, hepatitis B surface antigen (HBsAg)-
rriers, and the risk of acquiring hepatitis in the health professions is presented. Hepatitis A (HA) and hepatitis B (HB) are caused by two different organisms; cross-immunity does not exist. Although both diseases are contracted by both fecal-oral and parenteral routes, the former is predominant in HA, and the latter in HB. Incubation time and the length of the infectious period of both diseases are discussed. HBsAg carriers may be symptom-free. Hepatitis viruses are relatively resistant to heat and chemical agents. The best method of avoiding transmission by way of fomites

is by use of disposable equipment. Physical sterilization methods offer better protection than do chemical methods. The causative agent of HA is generally only excreted briefly by patients except in carriers; however, the HB virus may persist in patients for a long time, serving as a constant source of infection. Persons in the health professions face the greatest risk of contracting viral hepatitis. Patients posing the greatest threat as sources of infection are, in order, chronic dialysis patients, drug addicts, hepatitis patients without demonstrable HBsAg, and HBsAg positive patients. Measures that should be undertaken in dialysis units to reduce the risk of transmission are outlined.

8483 SERO-EPIDEMIOLOGY OF ACUTE VIRAL HEPATITIS. (Ger.) Mueller, R.; Willers, H.; Hoepken, W. (Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, D-3000 Hannover 61, W. Germany). *Munch. Med. Wochenschr.* 120(15):517-520; 1978.

A sero-epidemiological survey was conducted of 329 patients from the Hannover area, comprising virtually all patients from this area with clinically demonstrated acute viral hepatitis in 1975. Antibodies to hepatitis A virus (anti-HA), cytomegalovirus, and the hepatitis B surface antigen (HBsAg) were determined in all sera; IgM levels were also measured. In HBsAg-negative sera, antibodies to HBsAg (anti-HBs) and to HB core antigen (anti-HBc) were determined also. The diagnosis of hepatitis A (56 cases) was made only in cases in which seroconversion or a fourfold increase in anti-HA titer was observed during the course of the disease; in cases in which only a single serum sample was available, the demonstration of increased IgM levels in addition to the presence of anti-HA sufficed for the diagnosis. Contamination of the population with hepatitis A virus was high and increased with age, despite the low incidence of acute hepatitis A disease. Hepatitis A patients contracted the disease by contact with hepatitis A infections or during trips to southern Europe. All HBsAg-positive cases in this study (211 cases) were recognized as hepatitis B, as neither seroconversion nor significant increases in anti-HA titer were measured during the course of the disease. Non-A, non-B hepatitis was diagnosed in 62 patients. Fifty percent of the hepatitis B patients and 42% of the non-A, non-B hepatitis patients had been exposed parenterally to potentially infectious agents.

8484 VIRAL HEPATITIS AND PREGNANCY. (Fre.) Merger, C.; Chadeyron, P. A.; Levy, J. (Hopital Foch, 40 rue Worth, F 92151, Suresnes, France). *J. Gynecol. Obstet. Biol. Reprod. [Paris]* 1(4):529-536; 1977.

The epidemiology, symptoms, and prognosis of mother and infant were studied in nine women who developed long-incubation viral hepatitis during pregnancy. Hepatitis B virus (HBV) infection was suspected in four patients who had been inoculated or had blood withdrawn, and contagious hepatitis possibly due to HBV was suspected in the other five patients, only two of whom were known to have been in contact wit a source of contagion. Hepatitis A virus was rule out as a cause because of the incubation periods s by these patients. Symptoms appeared in the 5th t 36th week of pregnancy and did not differ from tho usually observed in viral hepatitis. The disease lasted 15-30 days in seven of nine patients. Thre patients were treated at the onset with corticosteroids and one was treated with steroids after a relapse. Neither chronic hepatitis nor serious jaundice was observed in any of the nine patients. Of the nine women, five delivered premature infant (between 26 and 36 weeks of gestation), and premat ty was the primary determinant of fetal prognosis. infant born at 29 weeks was stillborn and death ma have been due to a small retroplacental hematoma associated with a placenta previa and inhalation of amniotic fluid rather than maternal hepatitis. The other infants were normal at birth and not unusually small for the length of the respective pregnancies. Microscopic examination of the nine placentas did not reveal any sign of viral infection. Neonatal progress of the eight surviving infants was slow; they required an average of 16.2 days to recover their birth weights. Excluding th icterus due to birth at 28 weeks, three infants we jaundiced for many days. Since premature delivery is the most serious complication of viral hepatiti in pregnancy, beta-adrenergic drugs should be used with caution in threatened early labor.

8485 MATERNAL TRANSMISSION OF THE HEPATITIS VIRUS: FREQUENCY AND CONSEQUENCES. (F Buffet, C.; Larouze, B. (Hopital Antoine-Beclere, 157 rue de la Porte-de-Trivaux, F 92141 Clamart, France). *Gastroenterol. Clin. Biol.* 1(12):1053-1 1977.

The literature on the transmission of hepatitis B virus (HBV) from the mother to the fetus or to th neonate is reviewed with respect to frequency, mo of transmission, and consequences. Studies from occidental countries show that hepatitis B surfac antigen (HBsAg), whose presence indicates exposur to the virus, is rare in infants with mothers who are chronic carriers of HBsAg but frequent when t mother had acute hepatitis during the third trime of pregnancy. Studies from oriental countries sh that there is a higher percentage of infants with HBsAg born to mothers who are chronic HBsAg carri The presence of HBsAg in the serum of the father no influence on HBsAg level in the infant. Transmission of HBV *in utero* is suggested by the fact that blood obtained from umbilical cord is positi for HBsAg, the frequency of this event varying f study to study. Some neonates have HBsAg-positi cord blood although their mothers were HBsAg-nega tive. Electron microscopy has revealed some of components of Dane particles in cord blood. Amn otic fluid has also been shown to be HBsAg-posit One study showed an elevated probability of an i fant being HBsAg-positive up to 6 months of age the cord blood was also positive. The possibili that HBV is transmitted from mother to infant vi blood ingested by the infant during birth or via penetration through skin scratches during early e considered. Transmission via maternal milk does t appear to occur since HBsAg has not been found human milk. Maternal transmission of HBV has no mediate serious consequences. Infants born to sAg-positive mothers are usually asymptomatic sAg carriers with moderate and fluctuating elevaons in transaminase levels. Chronic hepatitis ersistent or active) and cirrhosis seem to be re outcomes; hepatitis usually occurs between 2 d 5 months after birth and is serious, with risk hepatic coma, chronic hepatitis, and postnecrotic rrhosis. Malformations such as biliary atresia ve been found in infants born to mothers who were sAg-positive but statistical studies have not been rformed. The risk of primary liver cancer (PLC) greater when the mother is HBsAg-positive and the ther negative for antibody to HBsAg. Families of tients with PLC have elevated levels of HBsAg and tibody to HB core Ag.

36 IMMUNOLOGICAL ASPECTS AND PROPHYLACTIC AND THERAPEUTIC PROBLEMS OF VIRAL HEPATIS. (Ita.) Fiaccadori, F.; Pizzaferri, A. niversita degli Studi di Parma, Parma, Italy). *nerva Med.* 68(62):4153-4172; 1977.

oblems of viral hepatitis are reviewed and disssed emphasizing hepatitis antigens in serum, e immunological response (humoral and cellular) hepatitis, and prophylactic and therapeutic imications. Antibody to hepatitis B core antigen nti-HBc) appears to be an indication of active ral replication whereas antibody to HB surce Ag (anti-HBs) appears to signal a state induced immunity. The behavior of immunoobulins in acute and chronic hepatitis, the forion of cytotoxic immune complexes, and the imological cellular response are analyzed with ard to the relation between changes in the ime system and the clinical course of the disease. was found that, generally, IgA and IgG levels within normal limits, while IgM levels are hin the normal limits for patients who are HB rface Ag (HBsAg)-positive and are significantly evated for those who are HBsAg-negative. Stand- gammaglobulins are fairly effective against pe A hepatitis, and notable protection has been monstrated in chimpanzees by a vaccine against pe B. Standard gammaglobulins are ineffective HBsAg-positive hepatitis, but gammaglobulins om individuals with high anti-HBs levels in the ood are effective in such cases and have been ed successfully to treat fulminant hepatitis.

37 HUMORAL AND CELL-MEDIATED IMMUNITY TO HEPATITIS B VIRUS ANTIGENS IN ACUTE AND ONIC LIVER DISEASE. (Eng.) Aldershvile, J.; etrichson, O.; Hardt, F.; Nielsen, J. O.; Skinhoj, (Kommunehospitalet, DK-1399 Copenhagen K, Denk). *Scand. J. Gastroenterol.* 12(8):917-922; 7.

e specific humoral immune response to hepatitis virus (HBV) antigens (hepatitis B surface anti- [HBsAg], hepatitis B core antigen [HBcAg], and hepatitis B e antigen [HBeAg]) was correlated with the cellular immunity to HBsAg and the clinical course of the HBV infection. Twelve patients were investigated after clinical and biochemical recovery from acute viral hepatitis type B and 13 were examined during the acute phase of type B hepatitis; 13 other patients had chronic active hepatitis with or without cirrhosis, 8 patients had chronic active non-B liver disease, 10 patients had miscellaneous HBV-negative liver diseases, and 12 subjects were healthy volunteers. None of the 13 patients examined during the acute phase of type B hepatitis had antibody to HBsAg (anti-HBs), but all 12 convalescent patients had anti-HBs. All patients had anti-HBc at all phases of viral hepatitis. HBeAg was present transiently in one patient. A cellular immune response to HBsAg (migration index <0.93) was found in 4 of 13 patients during the acute phase and in 7 of the 12 patients in the convalescent phase. Seven patients were studied longitudinally for cellular immune response to HBsAg. During the acute phase, migration inhibition was found in two patients only. In contrast, at the time the HBsAg was cleared in six patients, five had a cellular immune response to HBsAg. One of the nonresponding patients developed persistent hepatitis B surface antigenemia, and the other patient had been HBeAg-positive for several weeks. After HBsAg clearance, the migration index returned to normal in all five patients with previous inhibition. Only one patient with chronic type B hepatitis showed a cellular immune response to HBsAg, which was similar to the findings in two patients in each of the two remaining groups. The latter results suggest that a cellular immunity to HBsAg is not a prerequisite for the development of these conditions.

8488 IMMUNOGLOBULINS IN SUBMASSIVE HEPATIC NECROSIS. (Eng.) Kaymakcalan, H.; Dourdourekas, D.; Szanto, P. B.; Ainis, H.; Steigmann, F. (Cook County Hosp., 1825 W. Harrison St., Chicago, IL 60612). *Am. J. Gastroenterol.* 69(3, Part 1):289-294; 1978.

Immunoglobulin levels were determined in 34 patients with acute viral hepatitis and correlated with other parameters such as the levels of serum total globulins, gamma globulins, hepatitis B surface antigen (HBsAg), and enzymes to determine whether the immunoglobulin levels could be of prognostic or diagnostic significance. Seventy-three percent of the 15 patients with typical acute viral hepatitis (as determined by liver biopsy) had a slightly elevated serum globulin level (mean 3.6 g/100 ml). IgG was elevated above normal in 13 of the 15, ranging between 1,325 and 2,450 mg/100 ml in these patients, and was normal in the other two (1,010 and 1,210 mg/100 ml, resp.). The IgM level was elevated in 14 patients, the mean level being 305 mg/100 ml in all these patients. Of the 19 patients with submassive hepatic necrosis, 47% showed low serum globulin levels (mean 3.21 g/100 ml). The IgG levels were below the normal range in seven patients, within normal limits in six, and slightly elevated in six. Among the latter six patients, three showed only very slight elevations (1,300, 1,360, and 1,385 mg/100 ml, resp.), whereas the other patients had levels of 1,475, 1,800, and 1,650 mg/100 ml, resp. The IgM levels were moderately elevated in 14 patients (mean 279 mg/100 ml). The difference between the IgG levels in the two groups was statistically significant ($p<0.01$). Only 31.55% of the 19 patients with submassive liver necrosis showed slight elevations of the IgG level, while 86% of patients with classical viral hepatitis had elevated levels. These results suggest that the differential diagnosis of submassive hepatic necrosis in viral hepatitis from classical viral hepatitis can be aided by determining the serum IgG level.

8489 ACUTE AND CHRONIC HEPATITIS REVISITED: REVIEW BY AN INTERNATIONAL GROUP. (Eng.) Scheuer, P. J.; Bianchi, L.; De Groote, J.; Desmet, V. J.; Gedigk, P.; Korb, G.; *et al.* (Royal Free Hosp., London NW3 2QG, England). *Lancet* 2(8044): 914-919; 1977.

The pathological features of chronic hepatitis and their importance in the development of cirrhosis are reviewed. The development of chronic liver disease following acute hepatitis is also discussed. Chronic persistent hepatitis is a term referring to portal inflammation, with preserved lobular architecture and little or no fibrosis. There is little likelihood of direct progression to cirrhosis. A new category, chronic lobular hepatitis (CLH) had been proposed to describe the liver lesion in patients with prolonged hepatocellular dysfunction in whom the pathological changes are mainly confined to the lobules. These changes comprise spotty necrosis and inflammation as found in acute viral hepatitis. Piecemeal necrosis and bridging necrosis are not regarded to be part of the CLH lesion. Chronic aggressive hepatitis (CAH) has been redefined as a chronic inflammatory and fibrosing liver lesion of varied etiology and variable histological features. The features common to all untreated examples are piecemeal necrosis together with new fiber formation and lymphocytic infiltration of portal tracts and lobules. Other infiltrating cells may also be found, and features of acute hepatitis may be superimposed. Passive septa formed by collapse after bridging or multilobular liver cell necrosis may be present. Cirrhosis is not a defining criterion but may develop. Signs of liver cell regeneration are usually seen in CAH, and the borderline between CAH and cirrhosis in the more severe cases is not sharp. The confluent type of necrosis (i.e., central-central bridging, central-portal bridging, or multilobular necrosis) seen in acute hepatitis is often followed by healing and sometimes by complete recovery. In piecemeal necrosis however, where there are portal-to-portal connections, the development of chronic liver disease is likely. The authors believe that the morphological feature of greatest importance in the evolution of chronic hepatocellular disease is the infiltration of the tissue by lymphocytes and plasma cells that accompanies piecemeal necrosis and probably represents a continuing immunological reaction, at least in viral cases. The process by which acute hepatitis evolves into chronic liver disease requires careful analysis in different centers, so that the natural history and response to treatment of the different components can be accurately determined.

8490 THE CLINICAL EVOLUTION OF VARIOUS FORMS OF HEPATITIS. (Ger.) Maier, K. P. (Medizinische Universitatsklinik, Hugstetter Strasse 55, 7800 Freiburg, W. Germany). *Therapiewoche* 28(5): 738-746, *passim*; 1978.

Two forms of acute hepatitis, hepatitis A (HA) and hepatitis B (HB), may be distinguished from each other on the basis of the presence of HB surface antigen (HBsAg) in the blood of HB patients and of HA antigen (HAAg) in the blood of HA patients. A third form, non-A, non-B hepatitis may also be distinguished and may be more than one entity; it appears mostly as post-transfusion hepatitis. In HB patients, antibodies to the HB virus (HBV) core antigen (anti-HBc) may be found in the serum even after HBsAg has disappeared. The antibody against HBsAg (anti-HBs), may appear months after an acute HB attack. In a patient with suspected acute hepatitis, the transaminase levels are determined first. The Australia antigen test for determination of HBsAg follows demonstration of high transaminase levels. If both tests are positive, the patient is classified as having acute HB. Ninety percent of acute hepatitis patients recover spontaneously; medicinal therapy does not exist for this disease. Some patients evolve chronic hepatitis; HB patients are more at risk than are hepatitis A patients in this respect. In cases of chronic hepatitis, the presence of HA or HB must be determined. If the disease is neither HB nor HA, it may be chronic aggressive hepatitis (CAH) or chronic persistent hepatitis; the former must be treated, while the latter generally heals itself. Therapy for CAH with transaminase levels more than 10 times the normal value, SGPT 5 times the normal value, and an increase in gammaglobulin levels consists of administration of prednisolone by itself or in combination with azathioprin generally for more than 1 yr.

8491 NON-A, NON-B HEPATITIS. (Eng.) Feinstone, S. M.; Purcell, R. H. (Natl. Inst. Allergy Infectious Disease, Natl. Inst. Health, Bethesda, MD 20014). *Ann. Rev. Med.* 29:359-366; 1978.

Evidence that at least one additional agent, antigenically unrelated to hepatitis A or B viruses, is etiologically responsible for human viral hepatitis is reviewed. The epidemiology of this non-A, non-B hepatitis resembles that of type B hepatitis more than that of type A disease. Non-A, non-B hepatitis frequently follows blood transfusion and can progress to a chronic state, which makes its control highly important. Attempts to identify an antigen specific for non-A, non-B hepatitis or to transmit the disease to nonhuman primates have so far been unsuccessful. The only known means to prevent this disease is by the exclusive use of volunteer sources of blood for

nsfusions. The efficacy of immune serum glob-
n in preventing non-A, non-B post-transfusion
atitis is poorly defined. Other nonspecific
hods for screening blood donors, such as
suring enzyme levels, are currently under in-
tigation.

2 IDENTIFICATION OF HEPATITIS A VIRUS IN
FECES: DIAGNOSTIC AND EPIDEMIOLOGICAL
UE. (Fre.) Coursaget, P.; Maupas, P.; Hibon, P.;
deau, A.; Sizaret, P. Y.; Despert, F. (Hopital
iatrique Gatien de Clocheville, F 37000 Tours,
nce). *Nouv. Presse Med.* 6(44):4109-4113; 1977.

presence of virions was detected by immunoelec-
n microscopy in the feces of 11/13 patients with
atitis A. Fecal samples were suspended in a hy-
lysate of lactalbumin, and the viral-containing
ction was concentrated by successive centrifuga-
ns. Polyethyleneglycol 6000 was added to the
al suspension to a final concentration of 10%.
viral particles were observed ultrastructurally
er adding anti-hepatitis A virus immune serum
epared from a patient with hepatitis A 2 months
er onset of icterus), incubation at 37 C for 1
concentration by centrifugation, and staining
h uranyl acetate. The two negative fecal samples
e collected 1 month after onset of clinical signs
hepatitis. Samples with highest concentrations
virus particles were collected during the pre-
eric phase of the disease. The limit of the
iod of detection of virus was 5 days after onset
jaundice. There appeared to be a correlation
tween elevation of SGPT level and the presence
virions. A kinetic study of the appearance of
tibodies was performed in one patient. Specific
tibodies against hepatitis A virus reached a
ximum 2 months from the time of onset of jaundice.

Chronic Hepatitis

8504 TREATMENT OF CHRONIC ACTIVE HEPATITIS: AN ANALYSIS OF THREE CONTROLLED TRIALS.

(Eng.) Wright, E. C.; Seeff, L. B.; Berk, P. D.; Jones, E. A.; Plotz, P. H. (Veterans Admin. Hosp., 50 Irving St., N.W., Washington, DC 20422). *Gastroenterology* 73(6):1422-1430; 1977.

Three controlled trials of the use of corticosteroids and cytotoxic drugs in the therapy of chronic active hepatitis (CAH) were analyzed as to whether the experiments are designed and executed according to current standards for a controlled study and whether the results can be applied to the entire spectrum of CAB. A trial of no therapy (27 patients) versus prednisolone (PS, 22) at the Royal Free Hospital (RFH) during 1963-1967, a trial of azothioprine (A, 25) versus prednisone (P, 22) at the King's College Hospital (KCH) during 1968-1971, and a trial at the Mayo Clinic (MC) that initially (1967-1970) involved placebo (17) versus P (18) versus A (14) versus P + A (14) and later (1967-1974) added the modality of titrated P on alternate days (PT, 31) with 16, 30, 13, and 30 patients in the other 4 groups, resp., are reviewed in detail. In the RFH trial, the mortality was 56% in the untreated group and 14% in the PS group ($p<0.001$); in the KCH trial, mortality was 5% and 28%, resp., in the P and A groups; in the MC trial, the mortality in the P and P + A groups was significantly lower ($p<0.05$) than in the placebo and A groups, and P + A was shown to be superior to PT in inducing histological remission while causing fewer adverse side-effects. When 16 separate factors of design and execution were assessed, the RFH trial met 5 and partially met 2, the KCH trial met 6 and partially met 3, and the MC trial met 12 of the criteria. Although some of the omissions were unavoidable and the perfect trial probably cannot be executed, the deficiencies must nevertheless affect the results, particularly the lack of a placebo-treated group in the RFH and KCH trials, which in essence tested only drug efficacy, whereas the MC trial also permitted an analysis of risk factors. Summarizing the results of these three trials, the authors conclude that the only CAH patients in whom the benefit from corticosteroid therapy has been shown to outweigh the potential drug toxicity are those who are symptomatic, hepatitis B surface antigen (HBsAg)-negative, and who have severe histological abnormalities (subacute hepatitis with multilobular necrosis or cirrhosis). The authors believe that the results of these studies cannot be applied to the entire spectrum of CAH as currently recognized; biochemical and serological screening procedures are now able to detect CAH among asymptomatic individuals, so that a further evaluation of corticosteroid therapy is required for patients who are asymptomatic, HBsAg-positive, or who have the milder histological lesion of CAH alone.

8505 D-PENICILLAMINE IN THE TREATMENT OF CHRONIC ACTIVE LIVER DISORDERS.

(Ita.) Manzillo, G.; Sagnelli, E.; Balestrieri, G. G.; Maio, G.; Izzo, C. M.; Romano, F.; *et al.* (Clinica delle Malattie Infettive dell'Universita di Napoli, Napoli, Italy). *Clin. Ter.* 82(2):117-126; 1977.

The effectiveness of D-penicillamine therapy in patients with chronic active liver diseases (CALD) was studied in 36 patients of whom 27 were hepatitis B surface antigen (HBsAg)-positive; 25/36 were treated with D-penicillamine for 6-12 months and 11/36 terminated the treatment before 6 months. A control group of 17 CALD patients was given placebo for 6-12 months; 15/17 were HBsAg positive. The study group was given D-penicillamine: 300 mg/day for 1 week, 600 mg/day for 1 week, 1,200 mg/day for 1 week, 1,800 mg/day for 4 weeks, and then maintained with 700-900 mg/day. They also received 300 mg/day of vitamin B_6 p.o. throughout the period of treatment. Patients treated with D-penicillamine, whether for 6 or 12 months, had a statistically significant reduction in levels of SGOT and SGPT ($p<0.01$ and $p<0.05$, resp.) Also the serum IgM levels were significantly lower in these patients than in the control group ($p<0.01$). Of the 25 treated for >6 months, histological activity completely disappeared in 7, was reduced in 4, did not change in 13, and increased in 1. In the control group, 4 had a reduction, 11 showed no change, and 2 had an increase in histological activity. Side-effects of the drug were skin eruptions, temporary granulocytopenia in the initial phase of treatment, and proteinuria with or without hematuria. The authors will consider D-penicillamine a valid therapeutic alternative to corticosteroids once their findings are confirmed in a larger series.

8506 SOME MORPHOLOGICAL DATA ON CHRONIC HEPATITIS.

(Ita.) Giarelli, L.; Bianchi, C.; Antonutto, G. (Istituto di Anatomia e Istologia Patologica dell'Universita, Trieste, Italy). *Minerva Med.* 68(55):3779-3784; 1977.

Morphological aspects of chronic hepatitis are discussed to contribute a clearer understanding to the term chronic hepatitis. A direct immunofluorescence technique using antibody to hepatitis B surface antigen HBsAg conjugated to fluorescein can detect HBsAg in biopsied liver tissue. In the case of granulomatous hepatitis, an etiological diagnosis is often not possible solely on the basis of morphology. In these cases, tuberculosis is often the cause. Important differences in evaluation tend to be made on biopsy and autopsy materials. With biopsies, there is a tendency to overevaluate the observed modifications, while there is a tendency to underevaluate abnormalities seen at autopsy. Problems are encountered when distinguishing between chronic hepatitis and myelolymphoproliferation. An 82-yr-old man was treated for chronic lymphatic leukemia with antimitotic and cortisone drugs. At autopsy, a generalized cryp tococcoidosis was discovered; accumulations of crypto cocci were visible in the intralobular regions of the liver. A biopsy of a 69-yr-old woman, for whom clinical and laboratory data strongly suggested eosinophilic leukemia, revealed large numbers of eosinophils along with other types of cells infiltrating the liver. The liver of a 77-yr-old woman with Waldenstrom's disease showed fibrosis and a lymphoid infiltrate in the portal spaces. At autopsy, a 54-yr-old woman who had suffered for a number of years with cryoglobulinemia had fibrotic portal spaces and a lymphoid infiltrate; the infiltrate was immunofluorescent IgM-positive. These data illustrate that there is a morphological continuum between certain forms of chronic hepatitis and hemolymphoproliferative disease, which makes it difficult to distinguish between these types of lesions. Morphological data can help determine the causes of these disease states.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

8509 DRINKING AND DIETARY HABITS AND PREVALENCE OF SOMATIC ABNORMALITIES IN CHRONIC ALCOHOLICS HOSPITALIZED FOR DETOXIFICATION. (Eng.) Wallerstedt, S. (Sahlgrenska sjukhuset, Univ. Goteborg, S-41345 Goteborg, Sweden). *Acta Hepatogastroenterol.* 25(1):6-12; 1978.

The alcoholic histories, drinking and dietary habits, and physical status of 61 male chronic alcoholics were studied within 3 days after the end of the last debauch. The mean duration of alcoholism was 11 yr. The duration of the debauches usually varied between 1.5 and 3.5 weeks. Forty patients were "intermittent drinkers," who did not admit any alcohol consumption between debauches. None of the patients had chronic liver damage, but steatosis was present in 23 of the 33 patients in whom a liver biopsy was carried out. Only one patient each was found to have fibrosis and cirrhosis, resp. The amount of steatosis was not correlated to any parameter concerning drinking or dietary habits. There were statistically significant correlations between the final daily amount of alcohol consumed and heart rate ($p<0.05$), between the duration of the last debauch and the systolic blood pressure ($p<0.05$) and the diastolic pressure ($p<0.01$), and between the presence of Dupuytren's contracture and the age of the alcoholic ($p<0.01$).

8510 CLINICAL ASPECTS OF ALCOHOLIC HEPATITIS: A REVIEW OF 26 CASES. (Eng.) Demeulenaere, L.; Van Waes, L. (Sint-Andrieskliniek, Krommewalstraat 9, B-8880 Tielt, Belgium). *Acta Gastroenterol. Belg.* 40(7/8):261-270; 1977.

The clinical features in 26 patients with biopsy-proven alcoholic hepatitis are reviewed. Only seven patients were hospitalized because of prominent liver-related symptoms (jaundice, ascites, or abnormal liver function tests). The onset of disease was mostly insidious, and weakness, anorexia, and weight loss were the most common complaints (experienced by 24, 22, and 16 patients, resp.). Right upper quadrant pain was present in 11 patients. The association of fever, abdominal pain, and jaundice in five patients made the differential diagnosis between hepatitis and a surgical biliary condition difficult. Six patients were seen in delirium tremens, and four presented with manifestations of hepatic encephalopathy. Three patients progressed to liver pre-coma or coma. Two patients each developed minor gastric bleeding associated with gastritis or diffuse s.c. hematomas secondary to clotting abnormalities. Hepatomegaly occurred in 16 patients, and 8 were found to have ascites. In five patients, ascites developed in the absence of cirrhosis; all had pericentral venous sclerosis on liver biopsy, and two also had a low serum albumin level. In six patients, spider angiomata occurred during the acute phase of the disease. SGOT and SGPT levels were elevated above 45 U in 81% and 65% of the cases, resp. Transaminase elevation was usually moderate, and rarely exceeded 10 times the normal upper limit. The gamma-glutamyltranspeptidase level was elevated in 93%. Alkaline phosphatase and bilirubin levels were elevated in 73% and 39%, resp. Two patients (one with cirrhosis) died during the acute phase. Both had marked jaundice, abdominal pain, tender hepatomegaly, and spiking fever on admission. Three of 10 patients with hepatitis and fatty liver who continued drinking progressed to cirrhosis and 1/10 to fibrosis after 3, 6, 8, and 48 months, resp. Four patients who stopped drinking had full clinical and biochemical recovery. Repeat biopsy in two patients who did not abstain showed persistent necrosis and inflammation, but a biopsy in one patient who abstained showed a normal liver. It is concluded that clinical symptoms and biochemical alterations are unreliable indicators of the degree of liver injury in alcoholic hepatitis.

8511 CLINICO-PATHOLOGICAL EXPERIENCE WITH ALCOHOLIC HEPATITIS.

(Eng.) McDonald, G. S. A.; Hourihane, D. O. (Div. Lab. Medicine, Trinity Coll., Dublin, Ireland). *Ir. Med. J.* 71(2):47-51; 1978.

A clinico-pathological study was carried out in 32 Irish patients, and differences between these patients and those reported in the American literature are discussed. The most common clinical findings in the 20 Irish patients in whom a liver biopsy was carried out were raised levels of serum enzymes (89%) and a palpable liver (74%). The most common findings reported in a series in the American literature were palpable liver (81%) and pyrexia (56%); the incidence in the American series of nausea and vomiting (55%), abdominal pain (46%), and leukocytosis (56%) was greater than in the Irish patients (35%, 26%, and 19%, resp.). Among the Irish patients, alcoholic hepatitis was diagnosed before the liver biopsy in only one instance. Among the 12 Irish patients in whom alcoholic hepatitis was discovered at autopsy, liver failure due to alcoholic hepatitis with or without liver cirrhosis was the cause of death in 6. Alcoholic hepatitis was recorded as a clinical diagnosis in only 1 of the 12 patients. The pathological diagnosis of alcoholic hepatitis was based on the presence of necrosis and polymorphonuclear infiltration of the parenchyma and portal tracts. Two patients with severe necrosis had central vein phlebitis. Mild to moderate fatty change was present in 30 cases, and severe fatty change occurred in the remaining 2 patients. In contrast, fatty change was present in only 87% of the American cases. Alcoholic hyaline was observed in 45% of the 20 patients who underwent biopsy and in 58% of the autopsy cases; the presence of alcoholic hyaline occurred with a similar frequency in the American series. Fibrosis was present in 85% of the liver biopsy specimens and in 63.9% of the American cases. It appears that the clinical symptoms of alcoholic hepatitis are somewhat less severe in Irish patients in comparison with those in American patients. Such a diagnosis should be considered in alcoholic patients with an enlarged tender liver and raised serum enzyme levels.

8512 ALCOHOLIC HEPATITIS: RECENT PROGRESS IN THE STUDY OF THE PHYSIOPATHOLOGY AND CLINICAL FEATURES OF LIVER DAMAGE INDUCED BY ALCOHOL.

(Ita.) Lovisetto, P.; Actis, G. C.; Ferraris, R.; Marchi, L.; Biarese, V. (Istituto di Medicina Interna dell'Universita di Torino, Torino, Italy). *Minerva Med.* 68(62):4127-4146; 1977.

Recent progress in the study of the physiopathology and clinical features of liver damage induced by alcohol is reviewed and discussed with respect to the metabolism of alcohol, the effects of alcohol on the liver, histological characteristics and histogenesis of acute alcoholic hepatitis, and clinical characteristics, laboratory reports, diagnosis, prognosis, and therapy of alcoholic hepatopathy. The clinical picture is usually marked by the sudden onset of nausea, icterus, painful hepatomegaly, fever, ascites, and signs of encephalopathy. Laboratory tests can reveal hyperbilirubinemia, elevated alkaline phosphatase levels, elevated gamma-glutamyl transpeptidase activity, and augmented levels of bile salts. Leukocytosis and hyperuricemia may also be present. Needle biopsy can reveal various degrees of qualitative and quantitative damage (vacuolar degeneration, steatosis, cell necrosis, inflammatory infiltration, and interlaminar hyaline sclerosis) that depends on the extent of alcohol intake. Mallory bodies associated with polymorphonuclear cell infiltration and centrilobular sclerosis are characteristic indications of alcoholic hepatitis. Steatosis is also a common and diagnostic result of chronic alcohol intoxication. Progress of the disease is dependent to a large degree on immunological considerations. Treatment consists of elimination of alcohol, rest, and dietary management (high-protein and high-caloric diet).

8513 BIOPSY-DEMONSTRATED HEPATIC CHANGES IN CHRONIC ALCOHOLISM.

(Ger.) Lorenz, G. (Pathologische Institut, Ernst-Moritz-Arndt-Universitat, Fr.-Loeffler-Strasse 23e, DDR-22 Greifswald, E. Germany). *Z. Gesamte Inn. Med.* 33(5):145-148; 1978.

To classify hepatic damage due to alcoholism, random adult liver biopsies obtained during a 5-yr period from 2,952 patients, 506 of whom were clinically demonstrated alcoholics, were examined histologically. Of the alcoholics, 473 were men. The histological findings permitted the grouping of the biopsies into four categories. The first category (showing liver changes with no specific outstanding disease findings) comprised 39% of the biopsies from alcoholic patients; the second (consisting of fatty livers) comprised 40%; the third (alcoholic hepatitis) encompassed 18% of the biopsies; and the fourth (demonstrating cir-

osis) comprised 3%. The mean age of persons
th alcoholic hepatitis was 40 yr in men, 45
women. Iron deposits, which are supposed
have great diagnostic value in determining
coholic hepatic damage, were present in 48%
the cases, and cholestasis was present in 20%.
coholic hepatitis developed in most cases in 10-
yr after the beginning of ethanol abuse. Fatty
ver originated predominantly in the abuse of
cohol.

14 ELECTRON MICROSCOPIC STUDY OF ALCOHOLIC LIVER DISEASE WITH SPECIAL ATTENTION TO
E CHANGES OF MESENCHYMAL CELLS OF THE LIVER.
ng.) Balazs, M.; Varkonyi, S.; Pinter, A. (Janos
sp., Diosarok u. 1, H-1125 Budapest, Hungary).
p. Pathol. (Jena) 14(6):340-350; 1977.

ver biopsy material from 48 patients with
ronic alcoholism was studied ultrastructurally by
ectron microscopy to observe how liver damage is
fluenced by the disease progression. The patients
re grouped on the basis of clinical and histological
iteria: group I, 16 patients and alcoholic fatty
ver; II, 11 patients, fatty liver with increased
senchymal activity; III, 6 patients, acute alcoholic
patitis; IV, 8 patients, chronic alcoholic hepatitis;
d V, 7 patients, alcoholic cirrhosis. Fat accumula-
on, mitochondrial alteration (swelling of mitochon-
ia and elongation and aggregation of cristae), and
cal cytoplasmic degradation were demonstrated in
l cases with similar frequency and severity and
ere not correlated with the clinical severity of
e disease. However, proliferation of mesenchymal
ells, signs of their secretory activity, and fi-
er formation did correlate with the progression of
e disease. In group I, an increase of perisinu-
oidal fat-storing cells was noted in many cases.
group II, the number of mesenchymal cells was
creased; cytoplasm was abundant and rich in organ-
lles. In group III, leukocytes were present in
e sinusoidal wall and a basement membrane de-
eloped along Kupffer cells without significant
evelopment of collagen fibers in the Disse space.
e most prominent feature in group IV was the en-
argement and proliferation of Kupffer cells; the
ytoplasm was very rich in organelles and collagen
undles were seen around the Kupffer cells. In
roup V, proliferation of Kupffer cells was promi-
ent, and many of the perisinusoidal cells were
imilar to fibroblasts and protruded deeply between the liver cells; broad collagen bundles were situated in the intercellular space of liver cells. This study suggests that between alcoholic hepatitis and alcoholic cirrhosis there is another stage, the chronic alcoholic hepatitis stage (closely resembling chronic aggressive hepatitis), whose main characteristic is not the severity of the injury of the liver cells but the great proliferation of mesenchymal cells and lymphoid infiltration. There may be prognostic value in identifying those alcoholics whose fatty liver is combined with increased mesenchymal cell activity at the beginning of liver disease, possibly marking the onset of chronic liver disease.

8515 ASSOCIATION BETWEEN HLA-BW40 AND ALCOHOLIC LIVER DISEASE WITH CIRRHOSIS. (Eng.) Bell, H.; Nordhagen, R. (Oslo City Hosp., Oslo 1, Norway). *Br. Med. J.* 1(6116):822; 1978.

LIVER AND BILIARY TRACT

Cirrhosis

519 THE MORPHOLOGY OF CIRRHOSIS: RECOMMENDA-
TIONS OF DEFINITION, NOMENCLATURE, AND
LASSIFICATION BY A WORKING GROUP SPONSORED BY THE
ORLD HEALTH ORGANIZATION. (Eng.) Anthony, P. P.;
shak, K. G.; Kayak, N. C.; Poulsen, H. E.; Scheuer,
. J.; Sobin, L. H. (Middlesex Hosp. Medical Sch., London, England). *J. Clin. Pathol.* 31(5):395-414; 1978.

Guidelines on the definition, nomenclature, and classification of cirrhosis, chronic hepatitis, and hepatic fibrosis are presented, taking into account comments and criticisms from a number of pathologists and hepatologists throughout the world. Cirrhosis is defined as a diffuse process characterized by fibrosis and the conversion of normal liver architecture into structurally abnormal nodules. The complete classification of cirrhosis in an individual case would take into account its morphological features, etiology, stage of evolution, activity, and complications. Among the systems of morphological categories currently in use, the division of cirrhosis into micronodular and macronodular forms is preferred. The former division is described as a cirrhotic liver in which nearly all nodules are less than 3 mm in diameter, whereas the latter is described as having many nodules over 3 mm. When micro- and macronodules are present in approximately equal proportions, the term "mixed" may be applied. Etiological diagnosis is usually reached by a combination of epidemiological, clinical, biochemical, immunological, and histological investigations. Established etiological associations include viral hepatitis, alcoholism, metabolic disorders, biliary disease, venous outflow obstruction, toxins and therapeutic drugs, and intestinal bypass surgery; debatable factors include autoimmunity, mycotoxins, schistosomiasis, and malnutrition. Types of cirrhosis of unknown etiology include Indian childhood cirrhosis, which has a well-defined pattern, and "cryptogenic" cirrhosis, which does not. Cirrhosis is easily identified at necropsy, but may be diagnosed by surgical wedge biopsy or needle biopsy. Helpful features for the recognition of cirrhosis in a needle biopsy specimen include presence of parenchymal nodules, differences in liver cell size and appearance, fragmentation of the biopsy specimen, fibrous septa, and altered architecture and vascular relationships. Complications of cirrhosis include ischemic necrosis, siderosis, biliary obstruction, and infection. Hepatocellular carcinoma in cirrhosis is often associated with liver cell dysplasia. Chronic hepatitis is defined as liver inflammation continuing without improvement for at least 6 months, and may be classified morphologically as chronic persistent or chronic active. Hepatic fibrosis is defined as the presence of excess collagen due to new fiber formation and is classified morphologically according to its location. In addition to the causes of cirrhosis, the following causes of hepatic fibrosis are recognized: congenital, metabolic, inflammatory, parasitic, toxic, vascular, and physical.

8520 CHRONIC NORMOPROTEINEMIC HEPATOPATHY. (Ita.) Buzzelli, G.; Gallerini, L.; Guarducci, A. M.; Laffi, G.; Mazzanti, R.; Smorlesi, C.; *et al.* (Istituto di Clinica Medica, Universita, Florence, Italy). *Recent. Prog. Med. (Roma)* 63(5):497-526; 1977.

The literature on normal serum protein levels in patients with chronic hepatopathy is reviewed, and data from a series of 8/121 patients with liver cirrhosis and 13/170 with chronic active hepatitis, all of whom had normal serum protein profiles, are reported. Diagnoses were based on clinical and laboratory findings, radiology, scintigraphy, and liver biopsies. With respect to cirrhosis, a comparison of patients with normal (6.55 ± 0.15 g/dl) and abnormal (6.49 ± 0.14 g/dl) serum protein levels revealed a statistically significant difference in the BSP retention test ($p<0.01$), in serum albumin level (3.81 ± 0.13 versus 2.99 ± 0.15 g/dl, resp., $p<0.01$), and in the levels of serum IgA (233.6 ± 51.4 versus 433.5 ± 67.2 mg/dl, resp., $p<0.05$), IgG (1,357.1 ± 132.5 versus 1,840 ± 143.8 mg/dl, resp., $p<0.05$), and IgM (127.9 ± 12.1 versus 262.4 ± 45.3 mg/dl, resp., $p<0.02$). Patients with cirrhosis and normal serum protein levels had normal protein electrophoretic patterns and normal serum levels of immunoglobulins. In chronic active hepatits, significant differences were found between patients with normal and with abnormal blood protein levels with respect to the total protein level (6.78 ± 0.12 versus 7.32 ± 0.14 g/dl, resp., $p<0.01$) and the IgG level (1,367.5 ± 124.5 versus 2,334.1 ± 193.4 mg/dl, resp., $p<0.01$). The antistreptolysin levels were elevated in patients with chronic active hepatitis and abnormal serum protein level ($p<0.01$). Follow-up of six of eight patients with liver cirrhosis and normal seru protein levels showed that one had retained a normal level for 1 yr, two for 18 months, two for 2 yr, and one for 3 yr. Follow-up of 13/13 patients with chronic active hepatitis and normal serum protein levels revealed that 6 continued to have normal levels for 6 months, 4 for 1 yr, 2 for 18 months, and 1 for 2 yr.

8521 TOPOLOGICAL ANALYSIS OF THE MORPHOGENESIS OF LIVER CIRRHOSIS. (Eng.) Takahashi, T. (Tohoku Univ. Sch. Medicine, Seiryomachi, Sendai, Japan). *Virchows Arch. [Pathol. Anat.]* 377(3):189-201; 1978.

Topological analysis of the morphogenesis of liver cirrhosis was carried out, using the total connectivity number pl, in the livers of six autopsy cases of chronic liver disease. The total p_1 amounted to 6,100,000 in chronic hepatitis of the periportal type and to 6,350,000 in portal cirrhosis, but to only 100,000 in posthepatic cirrhosis of the coarse-nodular type. In view of the similarity of values for p_1 in chronic hepatitis and portal cirrhosis, the forme is considered to give rise to the latter by continuous change in structure or through "piecemeal progression of the periportal lesion. Developmen of posthepatitic cirrhosis from chronic hepatitis is possible only through a substantial reduction in p_1, which is brought about by parenchymal necrosis that is extensive enough to cause multiple disconnection of the network.

8522 METABOLISM OF CARBOHYDRATES, ADMINISTER BY THE PARENTERAL ROUTE, IN PATIENTS WI CIRRHOSIS OF THE LIVER. (Eng.) Brodanova, M.; Brodan, V.; Filip, J.; Kordac, V.; Marecek, Z.; Kuhn, E. (Faculty General Medicine, Charles Univ. Prague, Czechoslovakia). *Acta Univ. Carol. [Med. (Praha)* 23(1/2):17-129; 1977.

tudy was conducted to evaluate metabolic re- nse to the parenteral administration of simple bohydrates in cirrhotic patients, to determine effect of tolbutamide and biguanide on this abolism, and to determine if the sugars were table for the treatment of patients with er cirrhosis. Groups of subjects, selected m 65 patients with morphologically confirmed er cirrhosis, received the following quanti- s of sugars and/or antidiabetic agents: a infusion (500 ml of 10% solution) of glucose over 30 min, 24 mg fructose (F) i.v. in a solution over 6 min, 50 g sucrose (S) i.v. a 10% solution over 10 min, 50 g F or 50 g itol (X) as a 10% solution over 30 min, each ar alone or after the i.v. administration of tolbutamide (T) or after the administration 260 mg/day of butyl biguanide for 1 week. surements of blood sugar, lactate (LA), uvate (PY), immunoreactive serum insulin (IRI), ctose, uric acid, and ammonia levels were made samples of venous blood collected during in- ion and for 45 min after infusion. Similar surements on healthy controls were available comparison. The blood sugar level rose after declined slightly after S and X, and was un- nged after F. T hastened the decline in blood ar level after G, and in the other sugars it led a decline of blood sugar below the initial level. lightly delayed the disappearance of blood ar after G, and produced a permanent rise blood sugar level after S. Serum IRI was hest after G, followed by F, X, and S. Tol- amide potentiated the IRI response during usion and during the subsequent 45 min. B uced the IRI increments after all sugars ex- t F. The LA increments were greatest after F, ghtly reduced by T, and increased by B. PY nges after F were always positive, and after X, ays negative. T and B gave a similar order of nge. The LA:PY ratio increased after all sugars was dependent on the amount of sugar. It was hest after F and lowest after G. T, and thus ulin, enhanced the sugar metabolism and gave s of retarding the release of gastrin from G ls and of inhibiting the action of gastrin on ietal cells, it may be difficult to reveal a ntitative relationship between the gastric G l and parietal cell populations.

3 THE EFFECT OF GLUCAGON ON FREE PLASMA AMINO ACIDS IN CIRRHOTICS AND HEALTHY TROLS.

(Eng.) Brodan, V.; Brodanova, M.; el, M.; Kuhn, E. (Inst. Clinical and Experimental icine, Budejovicka 800, Prague 4-Krc, PSC 14622, choslovakia). *Acta Hepatogastroenterol. (Stuttg.)* 1):23-29; 1978.

tial plasma amino acid levels and their changes er glucagon administration (1 mg by infusion) e studied in seven patients with compensated er cirrhosis and seven healthy controls after an rnight fast at absolute bedrest. Cirrhotic ients had significantly elevated basal levels of osine, citrulline, tryptophan ($p<0.01$), threo- e, phenylalanine, and methionine ($p<0.05$) and significantly lower levels of serine and ornithine ($p<0.05$). Total amino acidemia was significantly higher ($p<0.01$) in the cirrhotics (3.353 ± 0.234 mM) than in controls (2.978 ± 0.167 mM). Glucagon administration caused significant decreases in the levels of ornithine, leucine, lysine, histidine, arginine, methionine ($p<0.01$), alanine, glycine, valine, proline, glutamate, and citrulline ($p<0.05$). The initial concentrations of amino acids exhibited a negative correlation with the change in their concentrations after glucagon both in the healthy controls ($r=-0.766$, $p<0.001$) and in the cirrhotics ($r=0.591$, $p<0.001$); hence, the decrease after glucagon is a function of the initial concentration. Excluding cystine-cysteine (which increased) the mean percentage decline in total amino acid level was -14.57 ± 4.84% in controls and only -9.14 ± 5.85% in cirrhotics after glucagon, the difference between the two groups being significant ($p<0.01$). The percentage decrease in essential amino acids in each group was nearly the same. Serum ammonia levels increased significantly in both groups ($p<0.05$), while the serum urea level increased significantly ($p<0.01$) only in the healthy controls.

8524 HYDROELECTROLYTIC METABOLISM IN LIVER CIRRHOSIS: PHYSIOPATHOLOGICAL AND THERAPEUTIC ASPECTS OF THE REINFUSION OF CONCENTRATED ASCITIC FLUID.

(Ita.) Borghetti, A.; Fiaccadori, F.; Bruschi, G.; Coruzzi, A.; Guariglia, A.; Ghinelli, F.; *et al.* (Istituto di Semeiotica Medica, Universita degli Studi di Parma, Parma, Italy). *Minerva Med.* 69(1):53-66; 1978.

The acute effects of the reinfusion of concentrated ascitic fluid was determined in nine cirrhotic patients. During basal conditions, the plasma volume and the pools of the Na^+ and K^+ were evaluated in relation to total water volume with radioisotopic techniques. During reinfusion (10-12 hr), the elimination of Na^+, K^+, and H^+; the osmolar clearance; and the creatinine clearance were evaluated. During basal conditions, there were no significant variations in the blood concentrations of Na^+ and K^+ or in the osmolarity of the blood; the concentration of albumin was markedly low; the total body water was markedly elevated; the plasma volume and the sodium pool were augmented; the potassium pool was diminished; the ratio of plasma volume to the sodium pool was reduced; and renal function was reduced with respect to glomerular filtration. During the extraction-reinfusion treatment, there was no evidence of significant modifications of arterial pressure; the plasma volume was increased by 28%; the clearance of creatinine was significantly increased; and diuresis increased with respect to that in the pretreatment control period. After the treatment, the plasma volume remained elevated· the renal functions corresponded to those during basal conditions; and the volume of diuresis was reduced and returned (as in the period of pretreatment) to hypertonic conditions. These results should be taken into consideration when treating the ascitic syndrome.

8525 ALKALINE PHOSPHATASE ISOENZYMES IN LIVER CIRRHOSIS.

(Eng.) Burlina, A.; Bugiardini, R. (Centro Ospedaliero Borgo Trento, I-37100 Verona, Italy). *Enzyme* 23(2):121-126; 1978.

The origin and diagnostic and prognostic significance of the slow fraction (ALP_4) of alkaline phosphatase found in liver cirrhosis were investigated in sera from 114 patients with liver diseases. The isoenzymatic tracings of sera from 18 of the 49 patients with cirrhosis showed the ALP_4 band. In the presence of 5×10^{-3} M L-phenylalanine, sera with the ALP_4 band showed a mean residual phosphatase activity of 63.4-70.5% of the original activity, whereas sera without this band showed a mean residual phosphatase activity ranging from 74.3 to 85%. After heating sera without the ALP_4 band at 56 C for 10 min, normophosphatemic sera showed normal residual activity; hyperphosphatemic sera were notably thermoresistant, with residual activity between 30% and 52%. The sera with the ALP_4 band were thermolabile, with a residual activity ranging between 11% and 34.5%.

8526 EFFECTS OF MEDROXYPROGESTERONE ON THE LIVER FUNCTION AND DRUG METABOLISM OF PATIENTS WITH PRIMARY BILIARY CIRRHOSIS AND CHRONIC ACTIVE HEPATITIS.

(Eng.) Sotaniemi, E. A.; Hynnynen, T.; Ahlqvist, J.; Ahokas, J. T.; Puoskari, U.; Pelkonen, I. (Clinical Res. Unit, Univ. Oulu, SF-90220 Oulu 22, Finland). *J. Med.* 9(2):117-128; 1978.

Medroxyprogesterone acetate, a synthetic progestin, was administered to six patients with primary biliary cirrhosis (PBC) and chronic active hepatitis (CAH) to evaluate its therapeutic effect through analysis of liver function and drug metabolism. Before this trial, all patients except one had been treated with prednisolone, azathioprine, and/or phenobarbitol and had developed resistance and/or side-effects to these drugs. During treatment with doses of 10-15 mg medroxyprogesterone for periods of 8-76 months, liver function tended to normalize. Significant reductions in the levels of total serum bilirubin (from 29.0 ± 31.0 to 14.0 ± 14.8 μml/1, $p<0.05$), serum alkaline phosphatase (from 503.7 ± 411.8 to 369.5 ± 275.2 U/1, $p<0.05$), and BSP retention (from 27.4 ± 11.2 to 12.5 ± 10.2%, $p<0.03$) were noted. The levels of serum antibodies declined and the hepatic metabolic ability, as tested by serum albumin levels and indices of drug metabolism, improved. Serum albumin level rose from 41.7 ± 2.3 to 43.3 ± 2.8 g/l, $p<0.01$, plasma antipyrine half-life was reduced from 15.1 ± 7.1 to 7.7 ± 0.7 hr, $p<0.05$, and the cytochrome P-450 content of biopsy samples rose from 6.8 ± 1.5 to 10.5 ± 5.8 nmol/g during treatment. The subjective symptoms of the diseases decreased. The authors believe that the improved effect on the clinical condition of the patients may be due to the immunosuppressive effect of medroxyprogesterone compared with barbiturate treatment. The study shows that medroxyprogesterone treatment of patients suffering from PBC or CAH leads to the suppression of the immunological manifestations of the disease and may be a valuable alternative for patients who have developed resistance or undesirable reactions to previous therapy.

8527 SOMATOMEDIN IN CHRONIC LIVER DISEASE.

(Eng.) Marek, J.; Schullerova, M.; Schreiberova, O. (Third Medical Clinic, Charles Univ., Prague, Czechoslovakia). *Rev. Czech. Med.* 22(4):194-201; 1976.

Since recent studies have suggested that the liver is an important site of somatomedin formation, serum somatomedin levels were determined in 6 patients with cirrhosis, 3 patients with chronic hepatitis, and 13 healthy controls. The somatomedin level in each patient was markedly lower than the mean level in the healthy subjects. There was a significant correlation between the serum albumin levels and the somatomedin level in the patients with liver disease ($r=0.8653$, $p<0.01$). These results are consistent with the results of previous studies indicating that the liver is an important site of somatomedin synthesis.

8528 FORMATION OF VITAMIN D METABOLITES FROM ^3H- AND ^{14}C-RADIOLABELLED VITAMIN D-3 IN CHRONIC LIVER DISEASES.

(Eng.) Long, R. G.; Skinne R. K.; Wills, M. R.; Sherlock, S. (Royal Free Hosp., Pond St., London NW3 2QG, England). *Clin. Chim. Acta* 85(3):311-317; 1978.

The formation of 25-hydroxy vitamin D (25-OHD) and dihydroxyvitamin D metabolites was studied using a double-isotope method. To evaluate the hypothesis that there is a failure to form dihydroxyvitamin D metabolites in liver disease. Eight patients were studied; seven had primary biliary cirrhosis, and the eighth had cirrhosis due to chro active hepatitis. Four were vitamin D replete, and four were vitamin D depleted, as judged by the serum 25-OHD concentrations (<4.15% of 25-OHD dose/ serum). Three of the four vitamin D-depleted patients (including 2 with histological osteomalacia) formed radioactive 1,25-dihydroxycholecalciferol; one of the patients with a normal serum 25-OHD concentration also synthesized 1,25-dihydroxycholecalciferol, the mean maximum serum level being 4.03% of the dose/l serum in the four patients. 24,25-Dihydroxycholecalciferol was formed by all vitamin D-replete patients but not by any of the patients who were vitamin D depleted. 25,26-Dihydroxycholecalciferol was formed by all patients, except one who also formed no 1,25-dihydroxycholecalciferol. This study suggests that patients with liver diseas can form dihydroxy vitamin D metabolites.

8529 THE CIRRHOTIC PATIENT AND THE PORTACAVAL SHUNT IN 1977.

(Fre.) Huet, P. M.; Marleau, D.; Lavoie, P.; Tanguay, S.; Viallet, A. (Hopital Saint-Luc, 1058, rue St. Denis, Montreal, Quebec H2X 3J4, Canada). *Rev. Fr. Gastroenterol.* (131):29-36; 1977.

The results of portacaval shunts were evaluated in 30 patients in whom the procedure was performed be cause of liver cirrhosis and hemorrhage from esoph

geal varices. Ten patients also underwent arter-
alization of the portal vein. Prior to surgery,
he functional portal blood supply to the liver was
valuated by the uptake of indocyanine green (ICG)
y the hepatocytes or of ^{125}I-albumin by the Kupffer
ells. Of the 20 patients who had only the porta-
aval shunt, 19 survived 1-50 months (average, 18
onths). Hepatic encephalopathy developed in 7/19.
ll of the patients who developed encephalopathy had
minimal decrease in portal blood supply, with ICG
ptake values above 20% (average, 33.7%). The 12
atients who did not develop encephalopathy had ICG
ptake values below 20% (average, 11%). Of the 10
atients who had arterialization in addition to the
hunt, 7 survived 12-50 months (average, 24.3 months),
nd none developed encephalopathy. The values for ICG
ptake were low in three of seven patients and over
0% (average, 31.9%) in four of seven patients. This
tudy suggests several conclusions: (1) all patients
ho undergo portacaval shunts should have prior
tudies of liver hemodynamics, (2) patients with
epressed functional portal blood supply are less
ikely to develop hepatic encephalopathy than are
hose with normal supply, and (3) patients with a
inimal decrease in portal blood supply appear to
enefit from arterialization in addition to the
hunt, although further evidence for this conclusion
s needed.

8530 COINCIDENCE POSITRON IMAGING OF THE LIVER AND HEART FOLLOWING RECTAL ADMINISTRATION OF ^{13}N-AMMONIA IN LIVER CIRRHOSIS. (Eng.) Fukuda, N.; Tateno, Y.; Rikitake, T.; Matsumoto, T.; Tomitani, T.; Suzuki, K.; *et al.* (Natl. Inst. Radiological Sciences, Anagawa, Chiba-shi 280, Japan). *Radioisotopes* 26(12):872-875; 1977.

8531 HEPATIC CIRRHOSIS IN VARANASI (A HAEMOSTATIC APPRAISAL). (Eng.) Singh, D. S.; Dube, B.; Gupta, J. P. (JIPMER, Pondicherry, India). *J. Indian Med. Assoc.* 69(2):26-30; 1977.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

532 SURGICAL PROBLEMS OF PRIMARY SCLEROSING CHOLANGITIS. (Fre.) Salembier, Y.;
upont, A.; Bleuez, M.; Paris, J. (Cite Hospitaliere,
9, rue de la Louviere, 59000 Lille, France). *J.*
hir. (Paris) 114(6):451-460; 1977.

he clinical symptoms, pathology, differential
iagnosis, and treatment of primary sclerosing cho-
angitis are discussed and five cases are reported.
he cases included three women (ages 22, 21, and 43
r, resp.) and two men (ages 53 and 43 yr, resp.).
wo of the patients had typical symptoms such as
cterus, pruritus, bile retention with enlarged
nterlobular hepatic ducts, and hepatomegaly. The
ondition, described for the first time in 1924,
s characterized by a diffuse inflammation with
ibrous thickening and stenosing of the biliary
ucts in the absence of lithiasis. Primary scleros-
ng cholangitis affects men primarily (62.5% of
ases), whereas primary biliary cirrhosis affects
omen primarily (75% of cases). Additionally, in
he former entity, there are no antimitochondrial
ntibodies or xanthoma present, and pruritus is
ot a constant symptom (present in only 1/4 of the
ases). Microscopic examination of the liver shows
he biliary canals surrounded by a circular fibrosis.
ubmucosal and subserosal fibrosis with inflammatory infiltration is always observed in the extrahepatic ducts in primary sclerosing cholangitis and may only be observed there in some cases of primary biliary cirrhosis. Ulcerative colitis is associated with primary sclerosing cholangitis in about one of three patients. Treatment of choice is corticoids, specifically prednisolone, 10-25 mg/day, alone or with biliary drainage to relieve cholestasis. A biliary-gastrointestinal bypass may be performed at the convergence of the biliary ducts, but the surgery would deprive the patient of local treatment such as injection of cortisone into the biliary drain. Prognosis remains poor with average survival 4 yr from time of definitive diagnosis.

8533 INVOLVEMENT OF THE PANCREAS IN ACUTE CHOLECYSTITIS. (Ger.) Brunner, H.; Neher, M.; Schmidt, H. D. (Chirurgische Universitatsklinik, Langenbeckstrasse 1, 6500 Mainz, W. Germany). *Therapiewoche* 28(8):1419, 1422; 1978.

Involvement of the pancreas was found in 21 of 72 patients with acute cholecystitis. The pancreatic involvement was identified as an enzymatic shift without pathological substrate in the pancreas in nine cases, as accompanying pancreatitis in eight, as edematous pancreatitis in one, and as hemorrhagic necrotizing pancreatitis in three. In another series of 97 patients with pancreatitis (33 cases of edematous and 64 cases of hemorrhagic necrotizing pancreatitis), acute cholecystitis was found in 4 cases (1 in edematous and 3 in hemorrhagic necrotizing pancreatitis). Even though pancreatic involvement is rather frequent in choledocholithiasis, the pancreatitis in such cases is usually of canalicular genesis.

8534 THE PREREQUISITES FOR LOCAL LYSOLECITHIN FORMATION IN THE HUMAN GALLBLADDER. II. STUDIES ON THE POSITIONAL SPECIFICITY OF THE PHOSPHOLIPASE A ACTIVITY. (Eng.) Tagesson, C.; Norby, S.; Sjodahl, R. (Dept. Medical Microbiology, Univ. Linkoping, S-581 85 Linkoping, Sweden). *Scand. J. Gastroenterol.* 13(4):417-422; 1978.

The positional specificity of phospholipase A in human gallbladder epithelium was studied using biosynthetically radiolabeled diacylphosphoglycerides as substrates. When homogenized epithelial cells were incubated with ^{14}C-palmitate-labeled *Escherichia coli*, ^{14}C-phosphatidylethanolamine (^{14}C-PE) was degraded. During this degradation, ^{14}C-lyso-PE and ^{14}C-fatty acids were formed. When the homogenized cells were incubated with ^{14}C-oleate-labeled bacteria, ^{14}C-PE was degraded, but no ^{14}C-lyso-PE was formed. Instead, the formation of ^{14}C-fatty acids was increased. The pH optimum of ^{14}C-fatty acid synthesis with ^{14}C-oleate- or ^{14}C-palmitate-labeled bacteria was 7.0. Since ^{14}C-palmitate occupies predominantly the 1-acyl position and ^{14}C-oleate the 2-acyl position of the major *E. coli* diacylphosphoglycerides, these findings suggest that (a) the phospholipase attacks the 2-position of diacylphosphoglycerides and (b) a complete deacylation of diacylphosphoglycerides in the gallbladder wall is brought about by the combined action of phospholipase A$_2$ and a lysophospholipase, the latter having the ability to hydrolyze the 1-acyl-lysophosphoglyceride. It appears that the biochemical prerequisites for a local formation and degradation of lysolecithin in the gallbladder are met by the positional specificity of the enzymes present. This finding substantiates the hypothesis that lysolecithin is an adjustable mediator of aseptic cholecystitis.

8535 ENDOSCOPIC TRANSPAPILLARY SPLITTING OF A CHOLEDOCHOCELE. (Ger.) Miederer, S. E.; Lindstaedt, H.; Siedek, M.; Franken, Th. (Medizinische Poliklinik, Universitat Bonn, Wilhelmstr. 35, 5300 Bonn, W. Germany). *Dtsch. Med. Wochenschr.* 103(5):216-219; 1978.

A choledochocele with bile outflow obstruction from the biliary and pancreatic ducts was diagnosed by endoscopic retrograde cholangiopancreaticography in a 67-yr-old man who presented with radiating upper abdominal pain and a constantly elevated gamma-glutamyltransferase level 16 yr after cholecystectomy for cholecystolithiasis. After distention of the choledochocele with contrast medium, a papillotome was introduced through the papilla, and the choledochocele was split open. The patien required neither anesthesia nor an abdominal operation. There were no complications, and the patie experienced immediate complete cessation of the pains. The bile flow from both systems became normal.

8536 GRAY-SCALE ULTRASOUND B-SCANNING IN CAS OF CHOLELITHIASIS, ESPECIALLY WITH NEGA TIVE CHOLECYSTORADIOGRAM. COMPARISON WITH SURGICA AND RADIOGRAPHIC FINDINGS. (Ger.) Koppers, B. (Institut fur Rontgendiagnostik, Technische Univer sitat Munchen, Westendstrasse 85, D-8000 Munich 2, W. Germany). *Med. Klin.* 73(8):279-283; 1978.

The results of gray-scale ultrasound B-scanning w
compared with those of surgery and cholecystoradic
graphy in 37 patients. The gallbladder was visua
ized by ultrasonography in 36/37 patients. Surge
or radiography revealed no stones in 16 cases; th
ultrasonic scan was correctly negative in 14/16 c
and falsely positive in 2/16. Surgery or radiogr
revealed gallstones in 20 cases; the sonography w
correctly positive in 16/20 cases and falsely neg
tive in 4/20. The correlations between ultrasoun
and the other techniques were significant (p<0.00
The findings indicate the great diagnostic value
sonography, especially in the case of neagtive
radiography.

8537 ENDOSCOPIC PAPILLOTOMY AND REMOVAL OF GALLSTONES. (Eng.) Seifert, E. (Sta Krankenhaus Kemperhof, 1st Med. Klin., Koblenzer Str. 115, 5400 Koblenz, W. Germany). *Am. J. Gastroenterol.* 69(2):154-159; 1978.

The results, complications, and risks of endosco
papillotomy (EPT) in the treatment of choledocholithiasis or papillary stenosis in a total of 99
patients in nine centers in Germany are reported
The procedure was successful in 880 of the 955
cases. Choledocholithiasis was the most frequen
indication for EPT, being present in 743 patient
Seventy-seven percent of these 743 patients were
cholecystectomized. Papillary stenosis was the
indication for EPT in 14.7% of the cases and tu
in 1.3%. Choledocholithiasis was successfully
treated by EPT (either by spontaneous delivery o
by extraction) in 85.9% of cases. Complications
developed in 7.3% of the 880 cases. These inclu
perforation (13 cases), hemorrhage (16), cholangitis (13), pancreatitis (15), and stone impacti
following the procedure (6). In the remaining
case, the Dormia basket became impacted into the
common bile duct and had to be removed surgicall
Most complications occurred within 24 hr of the
procedure, only 12% occurring on the 2nd day.
Sixty-five percent of the complications were
treated conservatively, 5% endoscopically, and
surgically. Most hemorrhages were stopped cons
atively, and 9 of 13 perforations could be trea
in this manner. Cholangitis was reduced by the
introduction of an indwelling tube in the commo
duct immediately after EPT. All but one case o

ancreatitis was treated conservatively. The
ortality rate was 1.7%, and this was reduced to
.25% when patients who died of cardiac failure
ere excluded. The remaining causes of death in-
luded hemorrhage (1 case), septicemia (3), liver
bscesses (1), pancreatitis (3), peritonitis (1),
nd cholangitis (1). It is concluded that EPT is
seful in the treatment of high-risk but operable
atients with choledocholithiasis or papillary
tenosis.

538 A FOLLOW-UP STUDY OF LIVER FUNCTION TESTS
AFTER SURGICAL TREATMENT FOR GALLSTONE
ISEASES. (Eng.) Harada, T.; Sugaya, H.; Maehara,
.; Kimura, K.; Hisauchi, T.; Tajima, Y.; *et al.*
okkyo Univ. Sch. Medicine, Mibu, Tochigi, 321-02
apan). *Gastroenterol. Jpn.* 12(6):446-454; 1977.

lterations in liver function as measured by SGOT,
GPT, serum alkaline phosphatase, and serum bili-
ubin levels were studied in 204 patients during
he 1st month and in 113 patients up to 1 yr after
urgery for gallstone disease. Postoperative prog-
osis and subjective symptoms were collected by
questionnaire mailed to 201 patients 10 months
5 yr after surgery. At 1 month of follow-up,
04 patients were separated into five groups: A,
04 patients, liver function normal before and
fter surgery; B, 47 patients, liver function im-
roved after surgery; C, 14 patients, liver func-
ion transiently aggravated after surgery but later
mproved; D, 14 patients, liver function abnormal
efore and after surgery; and E, 25 patients, liver
unction obviously aggravated postoperatively. At
yr of follow-up, 113 patients were distributed
these five groups as follows: 69, 29, 20, 3, and
in A, B, C, D, and E, resp. In the patients
udied from 1 month to 1 yr after surgery, the
ncidence of liver dysfunction (patients classi-
ed into groups D and E) was higher in cases of
holedocholithiasis (28.6%) than in cases of chole-
ystolithiasis (12.0%); it was also higher in cases
perated by choledochotomy (17.6%) and with T-tube
rainage (21.5%) than in cases operated by chole-
ystectomy (8.8%), and in cases requiring blood
ansfusion (22.3%) than in cases without trans-
sion (12.0%). The effects of blood transfusion
d the presence of pathologic conditions requiring
ansfusion contributed to the high incidence of
normal liver function in the 18 cases with blood
ansfusion. The presence of acute biliary in-
ection requiring use of antibiotics also pro-
ced a higher incidence of liver dysfunction. The
erage operation time for patients in group A was
9.4 ± 43.1 min; this time tended to be longer in
e other groups (184.1 ± 91.5 min in B and 163.9
45.1 min in E). Thus, the location of gall-
ones, the surgical technique used, the operation
me, and the need for blood transfusion and for
tibiotics were found to influence the liver
nction parameters. The postoperative survey re-
aled a favorable prognosis in 73.2%, relatively
vorable in 17.1%, slightly poor in 8.0%, and
or in 1.2% of the 164 patients replying to the
estionnaire. Subjective symptoms reported diar-
ea (25.9%), back pain (25.9%), and abdominal pain
2.1%).

8539 DIET AND CHOLESTEROL GALLSTONES: A MULTI-CENTER STUDY. (Eng.) Sarles, H.; Gerolami, A.; Cros, R. C. (Unite de Recherches de Pathologie Digestive U-31 Inserm, 46, chemin de la Gaye, F-13009 Marseille, France). *Digestion* 17(2): 121-127; 1978.

The role of diet in the development of cholesterol gallstones was studied by comparing changes in mortality due to gallstones with changes in diet during recent years in the southeast of France, and by comparing diet with the prevalence of gallstones in seven countries. Statistics in France obtained between 1939 and 1971 show that total calorie, lipid, and animal protein intake increased markedly from 1943 to 1967. The onset of an increase in mortality due to gallstone disease began 6 to 7 yr after the onset of the dietary increases. A comparison of the incidence of gallstones found at autopsy in France, India, Japan, Portugal, South Africa, Sweden, and Uganda with the types of diets in these countries revealed that low-calorie, low-protein, low-lipid, high-vegetable content diets are associated with low incidences of gallstones. A positive correlation between calorie intake and gallstone incidence was found for calorie intakes lower than 3,000 kcal/day, whereas no such association was found for higher calorie intakes because incidence of gallstones then varies greatly. The results suggest that a hypocaloric diet associated with a low intake of fat and protein is protective against cholelithiasis.

8540 DIET AND CHOLESTEROL GALLSTONES: A FURTHER STUDY. (Eng.) Sarles, H.; Gerolami, A.; Bord, A. (Unite de Recherches de Pathologie Digestive U 31 Inserm, 46, chemin de la Gaye, F-13009 Marseille, France). *Digestion* 17(2):128-134; 1978.

The diets of two groups of women with cholesterol gallstones were compared with those of two groups of women without gallstones, to determine whether dietary factors influence the development of cholelithiasis. The total caloric intake, caloric intake excluding alcohol, carbohydrate intake, animal protein intake, vegetable protein intake, total protein intake, and fat intake in 202 women without gallstones were similar to those in 11 women with cholesterol gallstones. A similar study in 50 patients and 50 controls also showed no significant differences in the dietary intake in the two groups. The results of the present studies do not support those of studies following World War II, in which increased caloric intake after the war was followed by an increased incidence of cholelithiasis. It is proposed that undernutrition, as seen during the war, may reduce the chance of cholelithiasis in women.

8541 IN-VITRO STUDIES OF GALLSTONE DISSOLUTION: THE EFFECT OF ADDED HEPARIN IN BILE SALT SOLUTIONS. (Eng.) Furnival, C. M.; Burnett, W.; Green, M. K.; Selvage, N. C.; Cavaye, G.; Hardie, I. R. (Clinical Sciences Building, Royal Brisbane

Hosp., Brisbane, Queensland 4020, Australia). *Aust. N.Z. J. Surg.* 47(6):828-831; 1977.

The dissolving effect of four bile salt solutions upon gallstones was tested *in vitro* using syphonage to continuously fill and empty test chambers for a 10-day period. Solutions of sodium cholate (SC), sodium taurocholate (ST), sodium deoxycholate (SD), and sodium chenodeoxycholate (SCD), all 200 mM, were tested, and physiological saline (S, 0.9%), heparinized saline (HS, 100,000 IU/1), and lecithin (L, 100 mM) were used as controls; 226 stones from 38 patients were tested. No stones exposed to S, HS, or L lost weight. All stones exposed to bile salts lost weight (26% in SC, 26% in ST, 52% in SD, and 41% in SCD); the weight loss in SD was significantly greater than that in SC or ST ($p<0.01$). A combined solution of SC and ST produced a greater weight loss (38%) than did the components alone, but still less than did SD. The weight loss in SCD was significantly greater than that in ST or SC ($p<0.001$). Addition of H to solutions of SC or SD enhanced the weight loss of stones to 43% ($p<0.01$) or 77% ($p<0.05$), resp.; this enhancing effect persisted ($p<0.01$) when weight-matched stones from each of 10 patients were tested in the two solutions: in 9/10 cases, the H-enhancing effect on weight loss occurred. The addition of L to SC, SD, or SCD solutions produced a significant increase in weight loss only in the case of SC (36%, $p<0.05$), with slight increases in the other tests. Fragmentation occurred in 34 stones, with the greatest incidence in SD + H solution. The results suggest that the optimal solution for clinical use is a combination of SC and H because the possible toxic side-effects of SD + H preclude its use.

8542 CLINICAL STUDIES ON DISSOLUTION OF GALLSTONES USING URSODEOXYCHOLIC ACID. (Eng.)

Okumura, M.; Tanikawa, K.; Chuman, Y.; Koji, T.; Nakawa, S.; Nakamura, Y.; *et al.* (Fukuoka Univ. Sch. Medicine, 34 Nanakuma, Nishi-ku, Fukuoka, 814 Japan). *Gastroenterol. Jpn.* 12(6):469-475; 1977.

The clinical usefulness of ursodeoxycholic acid (UDCA) in the dissolution of gallstones was investigated in 74 patients with gallstones in functioning gallbladders who were treated for 6 months or more (mean duration of treatment, 8.5 months). All patients received 450 mg of UDCA daily. During the study, other choleretics, anticholesterol drugs, and thyroid hormones were not used. The size and number of gallstones were recorded by cholecystography, the criterion for drug efficacy being a reduction in stone size of at least 20% in diameter compared with diameter before treatment. The gallstones completely disappeared in 16 patients and partially dissolved in 16 others (effective rate, 43.2%). The gallstones remained unchanged in 35 patients and required surgery in 7. In 26 of 35 cases with gallstone symptoms, a marked reduction in the frequency and severity of symptoms was noted. UDCA effectiveness for total dissolution was significantly higher with smaller stones (33.3%, 18.2%, and 5.9% for stones <5, 6-10, and >11 mm, resp.) Large numbers of small-sized stones were most easily reduced, the effective rate for complete or partial dissolution being 21.4% for small (<2 mm), 24.0% for moderate (3-9 mm), and 38.1% for large (>10 mm) numbers of gallstones. The rate of complete disappearance in 24 patients with floating gallstones was 33.3% and 19.1% in 42 without floating gallstones. The effective rate for complete or partial dissolution was 27.3% among 22 patients with some calcification of gallstones and 52.5% among 46 patients without calcification. The disappearance rates in this study clearly exceed the rate of spontaneous disappearance of gallstones (about 7.8%). Administration o either chenodeoxycholic acid (CDCA) or UDCA produc a marked increase in excretion of UDCA in bile, di inished cholesterol saturation of bile, and ultima the dissolution of cholesterol gallstones. While was harmful to liver function and increased hemoly activity due to formation of increased amounts of thocholic acid, UDCA produced no significant chang in blood or liver function tests. UDCA appears to as effective as CDCA in the dissolution of gallsto with few side-effects (soft stools in 4 patients a constipation in 1).

8543 MODIFICATIONS INDUCED BY URSODEOXYCHOLIC ACID (UDCA) ON THE LIPID COMPOSITION OF BILE AND PLASMA IN PATIENTS WITH CHOLESTEROL GALLSTONES. (Ita.)

Salvioli, G.; Salati, R.; Lugli, R.; Fratalocchi, A. (Istituto di Clinica Medica Generale dell'Universita di Modena, Modena, Italy) *Gazz. Med. Ital.* 136(10):517-530; 1977.

The effect of ursodeoxycholic acid (UDCA) on lipi and cholesterol levels in bile and plasma and on gallstone dissolution was investigated in 18 patients with cholesterol gallstones (16 patients with gallbladder stones and 2 with common duct stones). The daily doses of UDCA used were 500 m g (8 patients), 600 mg/g (1), 700 mg/g (1), 800 m g (5), or 1,000 mg/g (3); the range was 6.6-15.6 kg. The lithogenic index (LI) was determined before and after 1-3 months of treatment. The LI decreased from an average value of 2.02 before treatment to an average value of 0.99 after treatment ($p<0.001$), whereas the percentage of biliary UDCA plus chenodeoxycholic (CDCA) increased from 46.4% to 72%. There was an important difference between the patients treated with 500 mg/g UDCA and those treated with greater doses: the former group had 38.94 ± 9.76 and 31.18 ± 7.95% UDCA and CDCA, resp., whereas the latter had 47.98 ± 10.9 and 26.56 ± 6.05% UDCA and CDCA, resp., after treatment. The lithocholic acid level showed no significant alterations after treatment. Radiological examination carried out every 4 months showed gallstone disappearance in two cases and reduction in five after 8-12 months of treatment. The liver function tests were unchanged during the treatment period. Bile triglyceride levels decreased significantly ($p<0.01$) due to a reduction in very low density lipoproteins, where as there were small increases in the phospholipi levels and in high density lipoproteins. Cholesterol levels decreased in both bile and plasma. A remarkable effect on the subjective symptoms was noted in all patients. No side-effects were recorded in any patient.

8544 THE EFFECT OF ORAL CHENODEOXYCHOLIC ACID ON CHOLESTEROL SOLUBILITY IN HEPATIC BILE. (Eng.) Matsushiro, T.; Kobayashi, N.; Suzuki, N.; Yamauchi, H.; Sato, T. (Tohoku Univ. Sch. Medicine, Sendai 980, Japan). *Tohoku J. Exp. Med.* 124(2):187-196; 1978.

To determine the optimum dose of chenodeoxycholic acid (CDCA) in cholesterol dissolution, 14 patients who underwent cholecystectomy with T-tube drainage for cholesterol gallstone disease received 250, 750, or 1,500 mg CDCA daily for 7 days, following clamping of the T-tube. Seven patients received the 250-mg dose, while the other seven received the 750-mg dose for 7 days; the dose was increased to 1,500 mg in the latter patients, and this dose was given for a further 7 days. Hepatic bile samples were taken daily from the day before treatment through the last day of treatment, by releasing the T-tube clamp. There were no significant changes in the bile cholesterol, phospholipid, or total bile acid content after treatment in any of the three treatment groups, nor in a control group of five patients. Cholesterol solubility was calculated as (B+P)/C, where B is total bile acids, P is the phospholipid level, and C is the cholesterol level in hepatic bile. Before treatment, solubility ranged between 5.3 and 6.0 in the treatment group, and the value in controls was 6.1. In the group treated with 250 mg of CDCA, the mean value was 11.0 ± 4.0 on the 2nd day, 10.4 ± 2.8 on the 4th day, and 9.6 ± 1.3 on the 6th day ($p<0.05$ in all cases). A significant increase ($p<0.05$) in cholesterol solubility was also found in patients treated with 750 mg on the fourth day, but no increases occurred in patients given 1,500 mg or in controls. When the doses were calculated in terms of body weight, increases in solubility were slight in the three patients receiving 4.5 mg CDCA/kg or less in the 250-mg/day group, the highest increase being only 70%. In the other four cases in this group, who were receiving 4.6 mg/kg CDCA or more, the increase was over 100%. Among the patients in the 750 mg/day group, three patients receiving 15.0 mg/kg or less showed a 0% increase or lower. Those receiving over 15.0 mg/kg did not show as dramatic a response as did those in the 250 mg/day group receiving 4.6 mg/kg CDCA or more. It is concluded that the optimum dose of CDCA for increasing biliary cholesterol dissolution is between 5 and 12 mg/kg. The only side-effect of CDCA was transient SGOT and SGPT elevation in a patient receiving 750 mg daily.

GENERAL

8563 CARCINOEMBRYONIC ANTIGEN (CEA) TEST AND OTHER IMMUNOLOGICAL INVESTIGATIONS IN THE FOLLOW-UP OF ADENOCARCINOMA OF THE GASTROINTESTINAL TRACT. (Ger.) Hasler, E.; Spengler, A.; Berchtold, R.; Brunner, K. W.; de Weck, A. (Onkologische Abteilung, Inselspital, CH-3000 Bern, Switzerland). *Schweiz. Med. Wochenschr.* 107(47):1683-1691; 1977.

The carcinoembryonic antigen (CEA) levels were measured in 40 patients with gastric adenocarcinoma and in 85 patients with colorectal adenocarcinoma before and after surgery. The CEA level was above normal (>2.5 ng/ml) in 24/40 patients with gastric adenocarcinoma before surgery; the other 16 patients had normal CEA levels (false-negative results). Direct correlation was found between the tumor size, distant metastases, prognosis, and operability on one hand and the CEA level on the other. Radical surgery was possible in 9/16 patients with preoperatively normal CEA levels, and in 3/24 patients with elevated CEA level. Among the patients with gastric adenocarcinoma who underwent radical surgery, the incidence of recurrences has been 2/9 in the case of initially normal CEA level, versus 2/3 in the case of initially elevated CEA level. The preoperative CEA level was elevated in 58/85 patients with colorectal adenocarcinoma and normal (false-negative) in the others. Radical surgery was possible in 25/27 patients with initially normal CEA level and in 30/58 patients with elevated CEA level. The preoperatively elevated CEA level dropped to normal or decreased after surgery, depending on how radical the surgery was, while the CEA level showed further increase in the inoperable patients. The increase in the CEA level during the follow-up period was the earliest sign of distant metastases in most cases. The CEA test is a valuable tool in the follow-up of patients with gastrointestinal adenocarcinoma.

8564 NECROTISING ENTERO-COLITIS FOLLOWING UMBILICAL VEIN CATHETERISATION. (Eng.) Shah, K. J.; Corkery, J. J. (Children's Hosp.,

dywood Middleway, Birmingham B16 8ET, England).
in. Radiol. 29(3):295-301; 1978.

fteen cases of neonatal necrotizing entero-
litis (NEC) following umbilical vein (UV) cath-
erization are reported. Ten patients had ex-
ange blood transfusions and the others had UV
fusions of bicarbonate, dextrose, or fructose
r respiratory difficulties, convulsions, or
poglycemia. Symptoms occurred from 12-72 hr
ter transfusion or infusion and included abdom-
al distention (15 patients), abdominal tender-
ss (9), bile-stained vomiting (9), constipa-
on (8), blood per rectum (4), abdominal mass
), and diarrhea (1). Twelve patients required
rgery. The mortality rate was 4/15 patients.
e initial diagnosis of NEC was usually made by
ain radiography. Radiological features in-
ided bowel obstruction (8), peritonitis (5),
cites (4), pneumoperitoneum (3), pneumatosis
testinalis (5), thumbprinting (1), abscess and
stula (2), and intrahepatic gas (1). Patho-
ical findings at operation or post-mortem exam-
ation showed ulcers, infarcts (the principal les-
s in NEC), perforations, peritonitis, pneumatosis
testinalis, congested vessels, and inflammatory
iltrate in vessel walls. In all the present
ses, the UV catheters had been introduced
ndly and their position had not been localized
diologically. When the course of the catheter
rough the UV-ductus venosus (DV)-inferior
a cava (IVC) segment is followed radiolog-
lly, the properly positioned catheter viewed
the antero-posterior projection curves gently
the right of the mid-sagital line at T12
el before entering the DV. The lateral
w determines the exact location of the catheter
; when properly placed, it should be in the
or even the right atrium. The difficulty of
perly positioning the UV catheter without
iological localization and the association of
alpositioned catheter with NEC are presented.
authors recommend radiological localization
a radiopaque catheter as a sensible pre-
uisite to beginning UV transfusion or infusion.
y note that the radiographs can be taken with
imal handling of the patient on a portable x-
machine.

5 PERSISTENT POST-ENTERITIS DIARRHOEA.

(Eng.) Zoppi, G.; Deganello, A.; Gaburro,
(Cattedra di Auxologia and Clinica Pediatrica
l'Universita, Policlinico Borgo Roma, 37100
ona, Italy). *Eur. J. Pediatr.* 126(4):225-236;
7.

groups of pediatric patients--A, 18 patients
months old; B, 30 patients 12-30 months old--
h chronic diarrhea following acute enteritis
e evaluated clinically, biochemically, and gas-
enterologically. The principal symptom in all
ients was mild but persistent diarrhea for 4.5
.7 and 12.5 ± 4.9 months in groups A and B,
). Growth was impaired in 12/18 patients in A
in 24/30 patients in B. Before hospitaliza-
, all patients had been treated with antimicrobial drugs and had received milk-free, high-fiber diets. Laboratory studies gave the following results in groups A and B: mean hemoglobin, 10.4 ± 0.9 and 11.8 ± 1.1 g/dl, resp.; RBC, 4.1 4.1 ± 0.6 and 4.4 ± 0.2 10^6/ml, resp.; SGOT level, 75.7 ± 5.3 and 63.5 ± 15.6 IU/l, resp.; SGPT level, 37.7 ± 4.6 and 28.0 ± 4.3 IU/l, resp.; and iron level, 65.7 ± 26.5 and 62.4 ± 24.5 mg/dl, resp. Bone age retardation of -2.7 ± 1.9 and -5.3 ± 2.9 months in groups A and B, resp., was demonstrated. Stereomicroscopy of the intestinal mucosal biopsy specimens showed subtotal mucosal atrophy with ridges or convolutions, types II-c and II-c-d, in 9/18 patients in group A and in 10/30 patients in group B. Completely normal mucosa was never found. Liver involvement was excluded (normal SGPT values) and gut inflammation was confirmed (elevated SGOT values and study of biopsy material). Normal fecal flora were detected by bacteriological examination of the feces in all patients, but the total counts for both aerobic and anaerobic organisms in the patients were significantly ($p<0.01$) higher than normal, indicative of an altered ratio between the normal components of the fecal flora. A new diet was built up (polysaccharides, then proteins, disaccharides and dilute cow's milk); improvement began within 1 week. A normal diet, restricted only in high-fiber foods, was then adopted. Slow normalization of the stools occurred within 1-3 months, and weight and height approached normal at the end of 1 yr. After evaluation of the factors known to cause chronic inflammation after an acute infection, the authors conclude that the cause of persistent diarrhea in the patients was chronic inflammation due to the alteration of the intestinal microflora by inappropriate diet and therapy.

8566 THE GASTROINTESTINAL LESIONS IN LEUKEMIAS.

(Jpn.) Hiroshige, Y.; Matsumoto, N.; Suetsugu, N.; Miwa, S.; Kaku, T.; Sasaki, K.; *et al.* (Yamaguchi Univ. Sch. Medicine, Japan). *Jpn. J. Clin. Hematol.* 18(7):861-867; 1977.

Gastrointestinal lesions were studied at autopsy in 51 cases of leukemia. The lesions included leukemic infiltration, ulcers, necrosis, and hemorrhage. Leukemic infiltration generally did not produce ulceration. There appeared to be a higher incidence of multiple ulcers (47.7%) in patients who had undergone combination chemotherapy. There was a frequent association between oral ulceration and bacterial or fungal infection at the site of the ulcers in these cases. These observations suggest that steroid therapy, combined chemotherapy, and gastrointestinal infection could be etiologic factors in multiple ulceration. Six patients had shown acute abdominal symptoms, consisting of oral ulceration, melena, shock, and marked neutropenia, at the terminal stage of their illness. Ileocecal or large intestinal necrosis associated with ulceration, pseudomembrane formation, and bacterial and/or fungus infection was observed in these patients. Gastrointestinal lesions were the direct cause of death in a total of 10 patients, with 8 dying from massive gastrointestinal hemorrhage.

8567 MORPHOLOGIC AND FUNCTIONAL STUDY OF THE SMALL INTESTINE IN MARASMIC PATIENTS.

(Eng.) Fagundes Neto, U.; Wehba, J.; Patricio, F. R. S.; Machado, N. (Escola Paulista de Medicina, Rua Botucatu, 720, 04023, Sao Paulo, SP, Brazil). *Arq. Gastroenterol.* 14(4):241-248; 1977.

Jejunal morphology and small intestine function (absorbance of d-xylose, sucrose, lactose, and glucose) were studied in 22 children (3-36 months old) with marasmic malnutrition and chronic diarrhea (4 also had bronchopneumonia). Jejunal biopsy was performed after a minimum fast of 4 hr. The villus/crypt height ratio was used to classify the patients into four morphological classes (degree 0, I, II, or III) according to a published criterion; there were 2, 4, 14, and 2 patients in these categories, resp. An overall decrease in the number of villi was observed in 12 cases; in 6 cases, the epithelium had become cuboid and in 1 case, pseudostratified. The inflammatory infiltrate showed distinct degrees of alteration, but in all cases eosinophils were found on the lamina propria of the intestinal mucosa. The average values for d-xylose in the blood 1 and 2 hr after the patients had swallowed a d-xylose dose of 15 g/m^2 of body surface were 24.8 ± 9.2 and 28.0 ± 8.2 mg%; the dose was given after a minimum 4-hr fasting period. Also after a minimum 4-hr fast, overload tests for sucrose, lactose (2 g/kg body weight) and glucose (1 g/kg) were carried out on alternate days. Of 17 patients with normal sucrose and glucose absorption curves, 8 had normal lactose absorption curves and 9 had flat lactose absorption curves; 4 patients had normal glucose absorption curves but flat sucrose and lactose absorption curves; and the remaining patient had flat absorption curves for all three sugars. Three children died of complications (*Enterobacter* septicemia in 1 and bronchopneumonia in 2). This study has revealed morphologic functional alterations, termed "decreased villus population," similar to changes seen in kwashiorkor in children with marasmic malnutrition. The malabsorption of lactose in 73% of these patients emphasized the necessity of considering exclusion of cow's-milk formula during treatment. Intensive medical care and an adequate diet can reduce mortality and hospitalization time in these patients.

8568 THE ZOLLINGER-ELLISON SYNDROME. REPORT OF ONE CASE AND REVIEW OF THE LITERATURE.

(Fre.) Sarrazin, R.; Dyon, J. F.; Bost, M.; Rossignol, A. M.; Rachail, M.; Fournet, J.; *et al.* (Centre Hospitalier Universitaire de Grenoble, 38700 La Trouce, France). *Ann. Pediatr.* 53(12): 863-874; 1977.

A case is reported of a 9-yr-old girl with the Zollinger-Ellison (Z-E) syndrome that was revealed by a bleeding duodenal ulcer, and reports in the literature on 19 children under 15 yr of age with the Z-E syndrome are reviewed. The patient presented with episodic abdominal pain unrelated to meals. Initial x-ray studies and a laparotomy failed to disclose any abdominal pathology. An ulcer of the duodenum was revealed on barium tran-
sit studies taken after the patient had two episod
of vomiting with hematemesis. The Z-E syndrome w
identified by radioimmunoassay studies of plasma
gastrin performed after fasting, ingesting a high
protein meal, or receiving i.v. calcium (12 mg/kg)
A nontumorous hepatomegaly and the duodenal ulcer
were observed during a second laparotomy. At fir
the pancreas appeared normal, but careful exploration disclosed an enlarged lymph node on the posterior surface of the pancreas next to the duoden
A total gastrectomy and excision of the head of t
pancreas and adjoining duodenum were performed.
Histological examination of the excised pancreas
did not reveal any abnormal parenchyma; however,
the retropancreatic lymph nodes were invaded by
an islet cell tumor. Serum gastrin levels fell t
normal postoperatively, and 27 months later remai
low. The literature reports only 7/19 children
with Z-E syndrome with tumors located in the pancreas; other sites included lymph nodes (6), live
(8), and the gastrointestinal tract (2).

GENERAL

Parasitology

8598 THE ENZYME-LINKED IMMUNOSORBENT ASSAY (ELISA) IN THE DIAGNOSIS OF AMOEBIASIS. (Ita.) Sorice, F.; Delia, S.; Vullo, V.; Ferone, U. (Istituto di Clinica delle Malattie Tropicali e Infettive, Universita di Roma, Roma, Italy). *Ann. Sclavo* 19(3):484-489; 1977.

The application of the new serological method, the enzyme-linked immunosorbent assay (ELISA), in the detection of *Entamoeba histolytica* antibodies is reported for 39 subjects (15 harboring *E. histolytica* trophozoites, 6 with acute enteric symptomatology of undiagnosed cause, 8 with other parasitic infections, and 10 healthy individuals). The test is performed by incubating dilute antigen with the serum to be tested for 3 hr at 37 C. A total human antiglobulin antiserum conjugated with alkaline phosphatase is added followed by the enzyme and, in approximately 15-30 min, positive sera are distinguished by their intense yellow color. The results are evaluated with a spectrophotometer. Of sera from 15 patients with *E. histolytica* trophozoites, the optical density (O.D.) values were 0.42-0.80 in 9 cases and 0.81-0.90 in 6 cases (the average value for this group was 0.70). In six patients with enteric symptoms, the O.D. values were 0.15-0.20 with a median value of 0.17. The eight patients with other parasitic infections had O.D. values of 0.12-0.20 with an average value of 0.18. The average O.D. value of the control group was 0.12. The differences in the values between those with *E. histolytica* infections, those with other infections, and the control group were statistically significant ($p<0.001$). It is concluded that the ELISA is useful in the diagnosis of *E. histolytica* infections.

8599 COMPARATIVE EVALUATION OF TINIDAZOLE AND METRONIDAZOLE IN THE TREATMENT OF AMOEBIC LIVER ABSCESS. (Eng.) Kundu, S. C.; Sen, A.; Bhattacherjee, T. D.; Dasgupta, D. P.; Majumdar, S.; Mookerjee, P. K.; *et al.* (Singh Hosp., E. Rly. Calcutta, India). *J. Indian Med. Assoc.* 69(6):127-129; 1977.

A randomized comparative clinical study of tinidazole (T) and metronidazole (M) in comparable cases of amebic liver abscess was carried out to evaluate objectively the therapeutic effect of, tolerance to, and acceptability of each drug. Patients with clinical features of liver abscess bu without serious complications and not moribund were selected for the study; further, these subjects either had not received or had failed to respond to any anti-amebic drug during the previous month. Nine patients each received either T or M (2 g once daily for 3 days, p.o., for both drugs) chloroquine, and/or emetine HCl, if necessary, to obtain a cure, and supportive nonspecific treatme as needed. Clinical assessment was carried out prior to and on the 5th, 10th, and 30th days afte treatment; therapeutic response was graded excellent, good, fair, or poor according to rapidity of response to the test drug, time until clinical cure, and need for auxiliary specific and/or nonspecific treatment. The responses to T were significantly different from those to M (excellent, and 2; good, 1 and 1; fair, 0 and 0; poor, 1 and resp., $p<0.05$ for excellent and good versus fair poor). One patient in each test group died. One tient in the T group and four in the M group complained of side-effects (anorexia in both groups nausea, giddiness, headache, and sleeplessness i the M group). Tinidazole is superior to metroni zole, and therefore is the drug of choice, in tr ing uncomplicated amebic liver abscess.

GENERAL

Regional Enteritis

CROHN'S DISEASE: A LONG-TERM STUDY OF THE CLINICAL COURSE IN 186 PATIENTS. .) Bergman, L.; Krause, U. (Univ. Hosp., Upp-, Sweden). *Scand. J. Gastroenterol.* 12(8): 944; 1977.

ries of 186 patients with Crohn's disease ted during the period 1956-1968 was followed During the follow-up period, 177 patients undergone resection or bypass surgery. The observation time in these patients was 10.5 The overall recurrence rate after resection 51%. Radical resection (i.e., all affected s resected together with a margin of at least m of microscopically normal tissue) was carried in 84 patients, and the recurrence rate was Among the 57 patients who underwent non-cal resection (i.e., all diseased bowel was removed or else a disease-free margin of less 10 cm on either side of the resection re-ed), the recurrence rate was 84%. Patients had undergone a primary radical resection ed fewer re-operations and had fewer recur-es and a better quality of life than patients a nonradical first operation. The total ality in operations or due to complications rohn's disease was 5.4%. The mortality in ection with the operative procedure was 3.4%. general health of the 165 patients examined in 1975 was estimated: 87% were in very good general health, 9.1% had moderate subjective symptoms, and 3.6% had pronounced subjective symptoms.

8608 REGIONAL ENTERITIS IN CHILDREN: CLINICAL AND ROENTGEN FEATURES. (Eng.) Franken, E. A., Jr.; Smith, J. A.; Fitzgerald, J. R. (Indiana Univ. Sch. Medicine, Indianapolis, IN). *CRC Crit. Rev. Diagn. Imaging* 10(2):163-185; 1977.

A study of regional enteritis (RE) or Crohn's disease diagnosed in 36 children at Riley Children's Hospital of Indiana University is presented. The clinical manifestations of the disease, type of involvement, gastrointestinal and systemic complications, roentgenology, and problems of differential diagnosis in these children and in 268 pediatric RE cases in the literature are compared and frequently contrasted with related findings in over 600 adult RE cases in the literature. About one-third of the 36 children initially presented systemic problems such as arthritis (3), growth failure (2), fever of unknown origin (4), anorexia nervosa (2), and other nongastrointestinal problems (3). Nonspecific abdominal pain occurred in over 80% of the cases. The disease was limited to the small bowel in 13 of the children and in 4 of these there was no involvement of the terminal ileum. Nine of the 36 had isolated colon involvement. The authors emphasize that in a child with gastrointestinal symptoms requiring roentgenographic investigation, it is of greater importance to examine the small bowel and colon for possible RE than to examine for duodenal and gastric ulcer. Where RE is suspected, a complete roentgenographic evaluation including standard barium studies of the stomach, small bowel, and colon are indicated initially with retrograde small bowel examination to confirm the diagnosis in borderline cases and to assess the extent of involvement. Once the diagnosis of RE is established, techniques of examination can be modified to reduce radiation exposure.

8609 ISOLATED COLONIC CROHN'S DISEASE: CLINICAL, RADIOLOGICAL, AND ENDOSCOPIC ASPECTS, DIAGNOSIS, AND EVOLUTION.

(Fre.) Julien, M.; Vignal, J. (Hopital Henri-Mondor, Creteil, France). *Rev. Prat.* 27(55):3817-3834, *passim*; 1977.

Various aspects of Crohn's disease (CD) are reviewed. Colonic CD can be segmental, multisegmental, or diffuse. The rectum is involved together with other areas of the colon in 35-40% of cases. Rectal involvement alone is exceptional and occurs in only 2-3% of cases. Diarrhea accompanied by abdominal cramps, and sometimes containing pus, are the usual clinical signs. Rectal bleeding is much more likely to occur with rectal involvement. Differential diagnosis of CD and other colitis, particularly ulcerative colitis, is discussed. Barium transit x-ray studies identify the type of lesions (ulcerations, "thumb-print" lacunae) and site of lesions (right colon, ileum). X-ray often fails to identify rectal lesions, which can be found by endoscopic examination and biopsy. The evolution of the disease is highly variable and difficult to predict. Complications such as occlusions, fistulae, abscesses, and colectasia occur frequently, and surgery may be required; however, pathology will recur in 50% of patients.

8610 DETERMINATION OF THE FAECAL EXCRETION OF LABELLED BILE SALTS AFTER I.V. ADMINISTRATION OF ^{14}C-CHOLIC ACID: AN EVALUATION OF THE BILE SALT MALABSORPTION BEFORE AND AFTER SURGERY IN PATIENTS WITH CROHN'S DISEASE.

(Eng.) Andersson, H.; Filipsson, S.; Hulten, L. (Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *Scand. J. Gastroenterol.* 13(2):249-255; 1978.

The value of a recently described technique for determining fecal bile salt loss in the study of ileal function was assessed. By measuring total fecal radioactivity, correlated to 24-hr enterohepatic circulation, following the i.v. administration of ^{14}C-cholic acid, bile salt malabsorption was evaluated before and/or after surgery in 80 patients with ileal or colonic Crohn's disease, and the results were related to the length of ileum diseased or resected. Before surgery, bile salt malabsorption was observed only in nine patients with terminal ileal inflammation, but no significant correlation was found between bile salt excretion and the extent of ileal disease. Twenty-one patients with ileal, 36 patients with ileocolic, and 9 patients with colonic disease were investigated after surgery. The percentage of administered bile salt excreted in the feces correlated well with the length of ileum resected ($r=0.79$, $p<0.001$). The correlation between fecal bile salt level and the length of the resected segment expressed in percentage of total small bowel length was of the same magnitude ($r=0.80$, $p<0.001$). The correlation between bile salt malabsorption and the length of ileal segment resected was about the same in ileostomy patients and in patients subjected to restorative operation. In 19 patients investigated both pre- and postoperatively, it was possible to compare directly the magnitude of the bile salt loss caused by the ileal disease and that caused by the resection. Irrespective of the preoperative level, the small bowel resection resulted in an increased loss of bile salts ($p<0.001$ When a similar comparison was made for fecal fat excretion and the results of the Schilling test, the results were less consistent. Three ileal function tests were carried out in 50 patients wit malabsorption due to resection of less than 10 cm of ileum. The Schilling test gave abnormal result in only 48%, whereas a fecal fat excretion test confirmed malabsorption in 64%, and the fecal bile salt test gave results indicative of malabsorption in 96%. The agreement between the three tests improved in patients with ileal resections of more than 60 cm. It is concluded that the determinatio of fecal ^{14}C-cholic acid is a more sensitive test than the Schilling test or the fecal fat excretion test, at least in those patients with ileal dysfunction due to ileal resection.

8611 TREATMENT OF CROHN'S DISEASE IN THE CHILD. 12 CASES.

(Fre.) Navarro, J.; Fontaine, J. L.; Mathe, J. C.; Girardet, J. P.; Pernin, P.; Mougenot, J. F.; *et al.* (Hopital Trousseau, 24 av. du Dr. A. Netter, F 75012, Pari France). *Nouv. Presse Med.* 7(3):183-188; 1978.

The results of the treatment of Crohn's disease i 12 children (7 boys, 5 girls; age range 6-17 yr) are reported. In the five patients treated prior to 1974, treatment consisted of a low-residue die milk deprivation, and sometimes i.v. feeding. Sa azosulfapyridine (100 mg/kg/day) and corticostero therapy (1.5-3 mg/kg/day) for 15 days/month were prescribed for four of five patients. Three of t five patients eventually required surgery because stenosis (2) or fistula (1). The more recently treated group of seven patients were fed by i.v. and/or constant-rate enteral feeding regimens for periods of 15-22 days and 15-510 days (average 12 days), resp. Constant-rate nutrition by gastric intubation was possible with the patient at home in three cases by use of portable pump. A low-residue, hypoallergenic diet was instituted at th end of parenteral and/or enteral feeding. Salazo sulfamide (100 mg/kg/day), metronidazole (20 mg/k and levamisole (3 cases only, dose not specified) were prescribed for these patients. Five of the ven patients in the recently treated group, follo ore than 1 yr, demonstrated a rapid weight gain, pearance of diarrhea and cramps, healing of muco- issures and anorectal fistulas, and in one case, pearance of duodenal stenosis. Enteral feeding ot well tolerated by adolescents in the group; er, children were more likely to accept medi- ns and protein hydrolysates by this route.

RESULTS OF TREATING THE ACUTE STAGE OF CROHN'S DISEASE BY A DIETARY REGIMEN.) Fromm, H.; Gebel, M.; Schroeter, U.; Canz- H.; Schmidt, W. (Medizinische Hochschule, Wiechert-Allee 9, 3000 Hannover 61, W. Ger- . *Dtsch. Med. Wochenschr.* 103(9):377-380;

ffectiveness of diet treatment during the phase of Crohn's disease (CD) was studied series of 23 patients. Fifteen patients ved at first exclusively parenteral feeding 0 kcal/day; 20% amino acids, 25% fats, 55% hydrates); the others received a balanced etic diet (Vivasorb) through a nasoduodenal . A low-residue diet was then introduced ally in all patients. The cardinal symptoms such as severe abdominal pain, diarrhea, plete ileus, and weight loss, responded ably in all patients. Postoperative fistulae d in two of three patients, but enterocutan- fistulae remained open in all of five patients, ugh the volume of secretion decreased dis- ly in four. During the follow-up (1-24 months, ge 9 months), the symptoms recurred in five nts, necessitating operative treatment in . The results indicate that diet treatment is an effective therapy.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20205

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX		
SUBJECT INDEX		

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. Fo journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotropic hormone
ADP	adenosine diphosphate
AMP	adenosine monophosphate
amp	ampere
ATP	adenosine triphosphate
A	angstrom
BSP	sulfobromophthalein
C	degrees centigrade
cal	calories
cc	cubic centimeter
cm	centimeter(s)
dl	deciliter
DNA	deoxyribonucleic acid
ED_{50}	median effective dose(s)
EDTA	ethylenediamine tetraacetic acid
e.g.	for example
EEG	electroencephalogram
ESR	erythrocyte sedimentation rate
g	gram(s)
µg	microgram(s)
Hz	Hertz
hr	hour(s)
Ig	immunoglobulin(s)
i.m.	intramuscular
i.p.	intraperitoneal
IU	international unit(s)
i.v.	intravenous
kcal	kilocalorie(s)
kg	kilogram(s)
K_m	Michaelis constant
LD_{50}	median lethal dose(s)
LDH	lactic acid dehydrogenase
m	meter(s)
M	molar; mole(s)
mM	millimolar; millimole(s)
µM	micromolar; micromole(s)
ma	milliampere(s)
mCi, µCi	milli-, microcurie(s)
mEq	milliequivalent(s)
mg	milligram(s)
ml, µl	milli-, microliter(s)
mm	millimeter(s)
mOsm	milliosmolar; milliosmeter(s)
msec	millisecond(s)
mV	millivolt(s)
min	minute(s)
MTD	maximum tolerated dose
NAD	nicotinamide adenine dinucleotide
NADH	reduced nicotinamide adenine dinucleotide
NADP	nicotinamide adenine dinucleotidephosphate
NADPH	reduced nicotinamide adenine dinucleotidephosphate
ng	nanogram (10^{-9})
nm	nanometer(s)
Pa	ambient pressure
PAS	periodic acid - Schiff
pg	picogram (10^{-12})
pgEq	picogram equivalent(s)
p.o.	orally
ppb	parts per billion
ppm	parts per million
r	Roentgen
RBC	red blood cells (erythrocytes), red blood count
resp.	respectively
RNA	ribonucleic acid
s.c.	subcutaneous
sec	second(s)
SGOT	serum glutamic-oxalacetic transaminase
SGPT	serum glutamic-pyruvic transaminase
U	unit(s)
UV	ultraviolet
V	volt
WBC	white blood cells (leukocytes), white blood count
yr	year(s)

978.

comprehensive qualitative and quantitative assess-
ent of the origin, the yield, and the biochemical
ntegrity of cells isolated from rat jejunum was
arried out. Cell isolation yielded cells that were
early all structurally intact, that represented the
hole of the population of cells originally present on
he walls of the villi of rat jejunum, and that were
lmost all columnar absorptive cells; the only other
ells present (in small numbers) were goblet cells and
BC. One possible reservation about the integrity of
he isolated columnar absorptive cells arose from the
bservation that some cells contained many more vac-
oles, especially in the supranuclear region, than
ould be expected from examination of sections of
imilar cells *in situ* in the intact intestine. The
solated cells retained a number of solutes (ortho-
hosphate, ATP, ADP, AMP, lactate) at intracellular
oncentrations exceeding those of the solutes in the
ncubation medium; each of these test solutes would be
xpected to pre-exist in the isolated cells or to be
enerated intracellularly during incubation. A
umber of solutes (α-methyl-D-glucoside, 3-*O*-
ethyl-D-glucose, D-galactose, L-valine, L-
eucine) were translocated from the incubation
edium into the cell and accumulated there at
concentration exceeding that found in the
edium. Two inhibitors of fatty acid catabolism
2-bromo-hexanoic acid and 4-pentenoic acid) failed
o prevent intracellular accumulation of α-methyl-
-glucoside, possibly indicating that the accumula-
ion process is independent of fatty acid catabolism
r that these inhibitors failed to penetrate the
solated cells. All other inhibitors tested (oua-
ain, cyanide, dinitrophenol, phlorhidzin, and
arbonyl-cyanide-*m*-chlorophenyl-hydrazine) had the
ame effects on α-methyl-D-glucoside accumulation
s would be expected from observations with more
omplex preparations of intestine. The failure of
uabain to give complete inhibition of intracellu-
ar methylglucoside accumulation suggested that
hese cells contain an ouabain-insensitive Na^+-de-
endent ATPase similar to that found in other tis-
ues. Isolated cells respired at a steady rate
18.6 ± 0.9 μmol O_2/hr/mg cell DNA) using endogenous
ubstrates; the addition of 5 mM L-glutamine stimu-
ated respiration (to 25 μmol O_2/hr/mg cell DNA),
pporting the previous suggestion that plasma glu-
mine might be an important respiratory substrate
r intestine. The addition of D-glucose stimulated
espiration and gave rise to increased lactic acid
oduction. Extracellular L-valine was incorporated
to cell protein. Intracellular ATP, ADP, and AMP
vels could be held constant, or changed in a pre-
ctable way. The observations suggest that
olated and incubated cells could be valuable for
e further exploration of the biochemical func-
ons of the small intestine.

8621 ULTRASTRUCTURAL MORPHOMETRIC INVESTIGATIONS ON NORMAL HUMAN LIVER BIOPSIES.

(Eng.) Roessner, A.; Kolde, G.; Stahl, K.; Blanke, G.; van Husen, N.; Themann, H. (Lehrstuhl fur Medizinische Cytobiologie der Universitat, Westring 3, 4400 Munster, W. Germany). *Acta Hepatogastroenterol.* 25(2):119-123; 1978.

Morphometric ultrastructural evaluations of liver needle biopsies from 14 normal human subjects were carried out to obtain baseline data for comparative purposes and to determine whether such evaluations yield reliable results in spite of the higher range of distribution in this material compared with experimental liver material. The data were related to one of two reference systems: (1) unit volume of liver tissue or (2) unit volume of hepatocytes. Liver tissue volume was subdivided into sinusoid volume (0.211 ± 0.025 ml/ml liver tissue), hepatocyte volume (0.785 ± 0.025 ml/ml), and bile canalicular volume (0.0043 ± 0.0005 ml/ml). The hepatocyte cytoplasm accounted for most of the hepatocyte volume (0.729 ± 0.025 ml/ml), while the number of hepatocyte nuclei was 123.02 ± 8.20 x 10^6/ml liver tissue. The surface area of bile canaliculi was estimated to be 0.0508 ± 0.0042 m^2/ml liver tissue (a minimum estimate). The hepatocyte volume contained 0.076 ± 0.003 ml/ml nuclei, 0.924 ± 0.003 ml/ml cytoplasm, 0.138 ± 0.005 ml/ml mitochondria, 0.0099 ± 0.0006 ml/ml microbodies, 0.0045 ± 0.0013 ml/ml fat inclusions, and 0.0056 ± 0.0017 ml/ml lysosomes. There were 201 ± 14 x 10^9 mitochondria/ml hepatocytes (with inner and outer mitochondrial membrane surface areas of 2.171 ± 0.134 and 1.162 ± 0.056 m^2/ml hepatocytes, resp.) and 55.49 ± 2.39 x 10^9 microbodies/ml hepatocytes. The surface area of rough and smooth endoplasmic reticulum was 1.713 ± 0.140 and 1.981 ± 0.003 m^2/ml hepatocytes. The standard error of nearly all tested parameters was less than 10% of the mean, indicating that ultrastructural morphometric evaluations of normal human liver biopsy samples yield reliable results.

ABSORPTION - EXCRETION - TRANSPORT

8630 SIMILARITY IN EFFECTS OF Na^+ GRADIENTS AND MEMBRANE POTENTIALS ON D-GLUCOSE TRANSPORT BY, AND PHLORIZIN BINDING TO, VESICLES DERIVED FROM BRUSH BORDERS OF RABBIT INTESTINAL MUCOSAL CELLS. (Eng.) Toggenburger, G.; Kessler, M.; Rothstein, A.; Semenza, G.; Tannenbaum, C. (Laboratorium fur Biochemie, Eidgenossische Technische Hochschule, Universitatsstrasse 16, CH 8092 Zurich, Switzerland). *J. Membr. Biol.* 40(3):269-290; 1978.

To elucidate the role of Na^+, Na^+ gradients, electrical potentials, and anion substitution on sugar transport and on phlorizin binding, kinetic studies were conducted in vesicles derived from brush borders of rabbit intestinal mucosal cells. Phlorizin (20 and 100 mM) strongly inhibited D-glucose (30 μM) uptake by the vesicles under a 100 mM inward NaSCN gradient. Under equilibrium conditions, a large amount of low affinity phlorizin binding to intestinal brush border vesicles was observed, but there was no evidence of a high affinity component that could be correlated with the high inhibitory potency of the phlorizin. In the presence of a transmembrane NaSCN gradient, the rapid high affinity binding of phlorizin was observed within 1 sec. D-glucose abolished the high affinity component to the extent of about 80%; low affinity binding was not significantly reduced by D-glucose. Phlorizin binding was markedly reduced by substitution of NaCl for NaSCN or by allowing the vesicles to equilibrate in NaSCN for 1 hr before the addition of phlorizin. Phlorizin binding was increased twofold by a 90 mM choline thiocyanate gradient in the absence of a Na^+ gradient. However, in the absence of Na^+, no increase in D-glucose transport or in phlorizin binding was observed. The involvement of the small intestinal Na^+-dependent monosaccharide transporting system in the high affinity phlorizin binding was demonstrated and phlorizin was shown to be a fully competitive inhibitor of the monosaccharide transport process. The effect of the potential gradient ($\Delta\psi$), studied independent of an inward Na^+ gradient, showed $\Delta\psi$ to be a necessary factor in determining high affinity glucose-protectable phlorizin binding, but Na^+ must also be present. Furthermore, Na^+ alone without $\Delta\psi$ does not produce optimal high affinity glucose-protectable phlorizin binding. Three models attempting to integrate $\Delta\psi$ and Na^+-dependen of high affinity phlorizin binding with the mechanism of Na-dependent monosaccharide transport are proposed. The available experimental evidence doe not favor any one of these models. The complex nature of the phlorizin dissociation function was shown was well as the importance of the

erimental conditions in its determination. Both
presence of Na^+ and of an electrical trans-
brane potential difference are required for op-
al D-glucose-protectable phlorizin binding to
sh border membranes from rabbit small intestine.
orizin is bound to the D-glucose transporting
tein.

1 EFFECT OF ANIONS ON AMILORIDE-SENSITIVE,
ACTIVE SODIUM TRANSPORT ACROSS RABBIT
ON, IN VITRO: EVIDENCE FOR "TRANS-INHIBITION"
THE Na ENTRY MECHANISM. (Eng.) Turnheim, K.;
zzel, R. A.; Schultz, S. C. (Univ. Pittsburgh,
. Medicine, Pittsburgh, PA 15261). *J. Membr.*
l. 37(1):63-84; 1977.

effects of replacing Cl with sulfate, isethio-
e, hydroxypropane-sulfonate (HPSA), ethane-sul-
ate (ESA), or *p*-phenolsulfonate (PSA) on active
nsport (J_{net}^{Na}) were investigated in strips of
bit descending colon. Replacement of 107 mM
in the bathing solutions with isoosmolar sulfate,
thionate, HPSA and, to a lesser degree, ESA stimu-
ed J_{net}^{Na} when the basolateral pump mechanism was
saturated. These effects were rapid in onset
were readily reversible. These stimulatory
ons decreased the resistance of the amiloride-
sitive Na entry step at the mucosal membrane.
ever, when the active Na pump mechanism at the
olateral membrane was saturated, the stimulatory
ons did not decrease the resistance of the Na
ry process. These findings suggest the presence
a negative feedback system between the activity
the pump mechanism and the resistance of the Na
ry step, which may be mediated by the size of
intracellular Na transport pool. In other words,
seems that when the basolateral pump is operat-
at its maximal rate, the resistance to Na entry
ss the mucosal membrane through the amiloride-
sitive pathway is at a minimum and cannot be
ther decreased.

2 REVERSIBLE INHIBITION OF SODIUM ABSORP-
TION IN THE RAT COLON BY LOW pH: A MECH-
SM FOR DIARRHEA. (Eng.) Chung, R. S.; Johnson,
M. (Veterans Admin. Hosp., Iowa City, IA). *Surg.*
um 28:435-437; 1977.

effect of acidic pH on ion transport *in vivo*
studied in male Sprague-Dawley rats in which
cm of proximal colon were cannulated and per-
ed after the rats had been injected with keta-
e (40 mg/kg, i.m.). The pH of the perfusate
6.7-7.1 (control), 4.5, 3.0, 2.3, or 2.0. Net
fluxes were measured. H^+ disappearance was
early related to luminal pH (r=0.942, p<0.001).
net absorption of Na^+ and Cl^- and the volume
rption observed in the controls was decreased
reversed by decreasing pH; net secretion of Na^+
observed below pH 3 (p<0.01), net secretion of
began between pH 3.0 and pH 2.3, and net volume
retion was observed below pH 4.5 (p<0.01). His-
gical studies showed that structural damage of
rficial cells occurred with increasing severity
H decreased, beginning at pH 3. The initial
potential difference (PD) was greater at lower pH; PD decreased slowly during all experiments, with larger decreases at lower pH. It is suggested that PD may account for the major portion of H^+ movement, that net Na^+ movement may occur passively by paracellular shunt pathways, or that a much lower pH is required to affect Na^+ cellular transport, and that Na^+ and volume absorption changes driven by reduced pH may play a role in the diarrhea seen in clinical states of reduced pH in the colonic lumen.

8633 ABSORPTION OF PANCREATIC LIPASE FROM THE DUODENUM INTO LYMPHATICS. (Eng.) Papp, M.; Feher, S.; Folly, G.; Horvath, E. J. (Hungarian Acad. Sciences, P.O. Box 67, H-1450 Budapest, Hungary). *Experientia* 33(9):1191-1192; 1977.

To study the absorption of pancreatic enzymes, lipase activity was determined in the duodenal lymph and in the blood plasma of the femoral artery of dogs prior to and during maximal hormonal stimulation of exocrine pancreatic function. Duodenal lymph was collected in anesthetized dogs first for 90 min during saline infusion and then for 120 min during and after stimulation of exocrine pancreatic secretion by the i.v. infusion of 4 U/kg secretin and pancreozymin. Arterial blood samples were collected before, at 20, 40, and 60 min during stimulation, and at 90 and 120 min after stimulation. The mean basal pancreatic lipase activity was significantly higher in the duodenal lymph than in arterial blood plasma (p<0.01). When hormonally stimulated pancreatic juice was secreted into the duodenum, lipase activity was significantly elevated both in the duodenal lymph (p<0.01) and in each of the plasma samples (p<0.01) as compared with the initial values. Under these conditions, the mean pancreatic lipase activity in the duodenal lymph samples was significantly higher (p<0.01) than in the plasma samples. These results are thought to reflect pancreatic lipase absorption by the duodenum into lymphatics.

8634 DIPEPTIDE TRANSPORT IN THE INTESTINAL MUCOSA OF DEVELOPING RABBITS. (Eng.) Rubino, A.; Guandalini, S. (Second Sch. Medicine, Naples, Italy). *Ciba Found. Symp.* 50(New Series): 61-77; 1977.

The transport and selective carrier mechanisms of two dipeptides, glycyl-L-proline (G-pr) and glycyl-L-phenylalanine (G-ph), across the small intestinal brush border were studied in fetal, newborn, and suckling rabbits. G-pr is transported intact across the brush border, while G-ph is hydrolyzed at the border and the amino acids then transported across the brush border. Using glycine-labeled G-pr and phenylalanine-labeled G-ph, the intestinal uptake of each substrate was calculated from the amount of radioactivity in the tissue at the end of a 60-sec incubation period and compared with the uptake of the corresponding free acid. No significant differences in the uptake of free glycine in either ileum or jejunum were observed, but G-pr uptake showed a striking perinatal peak with a gradual increase from the 25th day of gestation, remained constant during the first 6 postnatal days, and then declined to reach adult values at 50 days after birth. G-pr transport proceeded by a single-carrier mechanism whose rate was stimulated by sodium ions. This transport did not appear to differ fundamentally from the influx process in adult rabbits, except that the maximal velocity was much larger in newborns than in adults (11.2 ± 2.5 and 0.81 ± 0.25 μmol/cm^2/hr, resp.). Affinity constants for G-pr uptake were 0.95 ± 0.26 and 0.91 ± 0.35 mM, resp., for newborns and adults. The two components of G-ph uptake were measured separately using a 40-fold excess of either G-pr or leucine as selective inhibitors of the intact peptide transport route and of the free acid transport after hydrolysis route, resp. Again, differences were noted between the uptake of free and dipeptide-bound phenylalanine. It was postulated that in fetuses the hydrolytic enzyme might not have developed and that it might develop completely only after birth. In newborn rabbits, the uptake of free amino acids was larger in the ileum, while the uptake of dipeptides was larger in the jejunum. Additional evidence of the distinction between the dipeptide and neutral amino acid transport processes was obtained in neonate rabbits; differences in the absorption of dipeptides and free amino acids along the length of the small bowel and a larger maximal velocity of the dipeptide carrier mechanism were observed in newborn rabbits. The findings may have significance in determining elemental diets for premature and full-term infants.

8635 EFFECTS OF INTRADUODENAL ACID ON GALLBLADDER NET WATER ABSORPTION AND MOTILITY IN THE CAT. (Eng.) Jansson, R. (Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *Scand. J. Gastroenterol.* 13(2):209-215; 1978.

Gallbladder absorption and motility were studied in anesthetized cats during the stimulation of gastrointestinal hormone release by intraduodenal acid infusion. Gallbladder function was studied with a perfusion technique that allows absorption and motility to be monitored simultaneously. The gallbladder is perfused at a constant rate from neck to fundus, and net water absorption is registered as a continuous decrease in weight on an electromagnetic balance. Hepatic bile flow is registered with a drop recorder. When the gallbladder was perfused by hepatic bile, the average net water absorption in the gallbladder was reduced from 0.60 ml/hr during the control period to 0.18 ml/hr ($p<0.01$) during HCl infusion (0.8 mmol/kg/hr). When the gallbladder was perfused by saline, intraduodenal acid infusion reduced net water transport from 1.34 ml/hr to 0.60 ml/hr ($p<0.01$). Acid infusion evoked a contraction of the gallbladder which, when estimated, expelled one-fifth of its contents. Bile flow increased from 1.37 ± 0.12 to 2.14 ± 0.16 ml/hr during acid instillation, and pancreatic secretion increased from 0 to 3.86 ± 0.77 ml/hr. The duodenal instillation of isotonic bicarbonate solution caused no changes in gallbladder net water transport, motility, or in bile or pancreatic secretion. A comparison of the present results with a study on the effects of i.v. secretin on gallbladder function suggests that the reduction in gallbladder net water absorption in response to intraduodenal acid can be explained by endogenously released secretin; the amount of secretin release evoked by acid infusion in this study can be assumed to be less than 2 U/kg/hr, since this amount reduced and even abolished absorption in the previous study. Gallbladder contraction observed after acid infusion may be explained by an endogenous release of cholecystokinin.

MOTILITY

8648 VAGAL INFLUENCE ON DUODENAL MOTOR ACTIVITY. (Eng.) Mir, S. S.; Mason, G. R.; Ormsbee, H. S., III (Univ. Maryland Sch. Medicine, Baltimore, MD). *Am. J. Surg.* 135(1):97-101; 1978.

The extrinsic and intrinsic vagal influences on duodenal motor activity were studied in the anesthetized dog to determine whether electrical vagal stimulation influences duodenal motility specifically via extrinsic fibers to the duodenum or through an intrinsic innervation that crosses the gastroduodenal junction. Dogs were vagotomized, and stimulating electrodes were placed on the distal cut ends of the vagal trunks. After truncal vagal stimulation at 32 Hz, 5 msec, and 3 mamp, the gastric antrum and the duodenum at 3 cm and 8 cm demonstrated significant increases in contractile activity ($p<0.001$ and $p<0.01$, resp.). Upon termination of the stimulatory current, poststimulatory contractions, or off responses, were frequently noted on the antrum and the duodenum. Significant poststimulatory activity was observed on the antrum in all phases of the experiment. After truncal vagotomy followed by extrinsic denervation of the duodenum (DENER), vagal stimulation produced an increase in motility index at the antrum ($p<0.001$) and at both sites in the duodenum ($p<0.01$). Off responses were still demonstrable early in the poststimulatory period in both organs. After truncal vagotomy, followed by DENER and then by pyloric transection (PT), vagal stimulation continued to produce an increased motility index at the antrum ($p<0.01$), but no increase in motor activity was seen in the duodenum. Off responses no longer appeared at either duodenal position upon termination of the stimulus current. After truncal vagotomy and PT, stimulus-induced contractions on the antrum and duodenum were still present. However, when truncal vagotomy was followed by PT and then by DENER, only the antrum responded with increased motor activity. These results support the concept that the motor innervation to the duodenum is composed of extrinsic vagal fibers and intrinsic vagal nerves that appear to first enter the antrum and then cross the gastroduodenal junction to innervate the duodenum.

8649 POTENTIATION BY DIPYRIDAMOLE OF THE INHIBITION OF GUINEA-PIG ILEUM TWITCH RESPONSE CAUSED BY ADENINE DERIVATIVES. (Eng.) Moritoki, H.; Kanbe, T.; Maruoka, M.; Ohara, M.; Ishida, Y. (Faculty Pharmaceutical Sciences, Univ. Tokushima, Shomachi-1, Tokushima 770, Japan). *J. Pharmacol. Exp. Ther.* 204(2):343-350; 1978.

The inhibitory actions of adenine derivatives on transmural-stimulated ileal contractions were studied in the guinea pig, and the potentiation of the effects of these derivatives by dipyridamole was investigated. Adenosine and adenine nucleotides caused dose-dependent inhibition of ileal contraction induced by transmural stimulation (twitch response) at 0.1 Hz. The inhibitory effects of the adenine derivatives were potentiated by pretreatment with dipyridamole at concentrations of over 10^{-8} M for 30 min. Dipyridamole shifted the dose-response curve for adenosine to the left with concentrations of 3 x 10^{-8} and 3 x 10^{-7} M dipyridamole causing about 8- and 13-fold shifts, resp. Tritium activity, which was accumulated during incubation of the ileal segments with ^{3}H-adenosine, was reduced by dipyridamole; 10^{-7} M dipyridamole reduced the ratio of tissue activity to activity in the medium (T/M ratio) from 8.09 ± 0.94 to 4.13 ± 0.59, while 10^{-6} and 10^{-5} M dipyridamole decreased the T/M ratio further to 1.79 ± 0.29 and 0.94 ± 0.12, resp. When a 10-ml sample of 10^{-4} M adenosine was incubated with 500 mg of ileal segment, about 50% of the adenosine in the medium disappeared in 5 min, with a slight concomitant recovery of the twitch response; 50% recovery occurred after 20 min. In the presence of 10^{-6} M dipyridamole, adenosine disappearance and recovery of the twitch response were much slower; 50% of the adenosine disappeared in 15 min, and 50% of the twitch response was restored in 60 min. It appears that dipyridamole potentiates the inhibitory actions of adenosine and adenine nucleotides on the ileal twitch response by inhibiting both the accumulation and the degradation of adenosine.

8650 ELECTRICAL ACTIVITY OF COLON OF THE NON-SEDATED DOG. (Fre.) Bueno, L.; Garcia-Villar, R.; Ruckebusch, Y. (Ecole national veterinaire, 23, chemin des Capelles, 31076 Toulouse Cedex, France). *C. R Acad. Sci. [D] (Paris)* 285 (16):1463-1466; 1977.

Electromyographic studies of the colon were performed on nonsedated dogs that were fasted or that had ingested a standard meal. Electrodes were implanted in 10 anesthetized adult dogs in the wall of the ileum 2 cm above the ileo-colonic junction and in the wall of the colon, 5, 10, and 15 cm below the junction. One week after the electrodes were placed surgically, a second was inserted rectally to the ileocolonic junction to introduce endoluminal electrodes for comparative recordings in the nonsedated state. Both the intraparietal and endoluminal electrodes recorded two rhythms of colonic slow waves, with frequencies of 5.1 ± 1.3 cycles/min and 18.1 ± 1.1 cycles/min, resp. The electrograms produced by the endoluminal electrodes differed in two respects from the intraparietal recordings: (1) the amplitude of the rapid rhythms was in the neighborhood of 0.2 mV compared to 0.1 mV measured by the intraparietal electrodes and (2) the slower rhythm was recorded less than 2% of the time and was apparently superimposed on the rapid rhythm. Brief salvoes (1.4 ± 0.3 sec) of the faster rhythms appeared to be preferentially recorded by the endoluminal electrodes. It is concluded that the faster rhythm of the colonic slow waves arises in the muscularis mucosae, which is isolated from the muscular fibers of the wall by the submucosa in the dog.

8651 RELAXATIONS MEDIATED BY ADRENERGIC AND NONADRENERGIC NERVES IN HUMAN ISOLATED TAENIA COLI. (Eng.) Stockley, H. L.; Bennett, A. (Charing Cross Hosp. Medical Sch., London, W6 8RF, England). *J. Pharm. Pharmacol.* 29(9):533-537; 197

To investigate relaxations mediated by adrenergic and nonadrenergic nerves in isolated human taenia coli, macroscopically normal specimens of human as cending, transverse, and sigmoid colon, obtained a operation for colonic carcinoma or Crohn's disease were studied. The strips of taenia responded to electrical stimulation at 4, 8, and 16 Hz with 0.3 0.5, and 1 msec pulses, but most were unaffected a 0.1 msec. The order of magnitude of maximal relax ations induced by adrenergic blocking drugs was norepinephrine (0.2-1 µg/ml)>nicotine (1-40 µg/ml)≈ATP (90-1,440 µg/ml)>electrical stimulation. Electrical stimulation in the presence of hyoscine (2 µg/ml) caused relaxation followed by a rapid "after-contraction." Adrenergic blockade by oxprenolol (0.6-6 µg/ml) or guanethidine (20-30 µg/ml) caused relaxations to ATP to increase in three and decrease in one of five experiments and to nicotine at 16 Hz to decrease greatly or be wholly prevented. Relaxations to the effects of the indirectly-acting sympathomimetics tyramine (0.8-4 mg/ml, 0.5-5 min contact) and nicotine (4 µg/ml) were studied to examine interactions between adrenergic and nonadrenergic inhibitory nerves. Tyramine caused contraction followed by relaxation after washout, or only a delayed relaxation; the contractions were unaffected by tetrodotoxin (TTX, 1 µg/ml), dihydroergotoxine (1 µg/ml), or oxprenol (5 µg/ml) and were enhanced by tranylcypromine (0. 800 µg/ml). Relaxations to nicotine increased wit contact time up to 4 min ($p<0.05$ for the differenc in response between each time period) and were reduced by TTX to 1%, 2%, 6%, and 10% of controls with 0.5, 1, 2, and 4 min, resp., of contact time. Nicotine-induced relaxations that persisted in the presence of TTX seemed mainly adrenergic since oxprenolol (3 and 15 µg/ml) reduced them to 21% and completely prevented them, resp. Thus, adrenergic relaxations during stimulation occur only with short electrical pulses at high frequencies or wit ganglion stimulants. The results with TTX and the sympathomimetics demonstrate that colonic adrenerg nerves are mainly preganglionic and possibly synap with nonadrenergic inhibitory nerves. When the latter undergo direct maximal stimulation, respons to adrenergic nerve excitation are masked.

A procedure for setting up a preparation of mammalian gastric mucosa from kitten or ferret is described, and the responses of both preparations to cholinergic, histamine, and pentagastrin stimulation were studied. The mucosa is stripped of its outer muscle coats except for a 2-mm strip of circular muscle fibers running across the diameter of the preparation. The connections of this strip to the underlying mucosa are undisturbed. The preparation is immersed on the nutrient side in Krebs-Henseleit solution gassed with 95% O_2 and 5% CO_2 and on the secretory side in 5% dextrose, with both sides at 37 C. Acid secretion is determined by a pH stat method, and motility is recorded by a strain gauge attached to one end of the muscle strip. Secretory and motility responses are recorded for the three main parietal cell agonists, acetylcholine (ACh), pentagastrin, and histamine. Ferret membranes displayed a spontaneous rate of secretion of between 0.6 and 1.8 μEq H^+/cm^2 hr with a mode near 1 μEq/cm^2/hr, while the kitten membranes exhibited basal rates of acid secretion having a similar range of variation with a modal value near 0.7 μEq/cm^2/hr. The greatest secretory response to acetylcholine (ACh) stimulation in the ferret membranes was seen with a concentration of 10^{-4} M; a mean plateau of secretion of 4.4 μEq/cm^2/hr was established within 16 min. Smaller responses were seen with lower (10^{-5} M) and higher (10^{-3} M) ACh concentrations. Fundic smooth muscle response to ACh was rapid, and onset consisted of an abrupt large increase in the amplitude of spontaneous contractions, which declined shortly thereafter, and of a more sustained increase in basal tension. Although only a small increase in secretion was seen after an ACh dose as high as 10^{-3} M in the kitten fundic membranes, the kitten and ferret membranes were not greatly dissimilar in their sensitivity to cholinergic stimulation; however, the stable choline ester, urecholine, had to be used before the acid secretory response was fully manifested in the kitten preparation. The mean plateau acid secretory responses to 6.51 x 10^{-7} and 6.51 x 10^{-8} M pentagastrin in the ferret were 4.6 and 3.9 μEq/cm^2/hr, resp. The contractile response was similar to that produced by ACh. The kitten membrane was less sensitive to the hormone, both in terms of secretory and muscle responses. Acid secretion increased to 3 μEq/cm^2/hr after stimulation with 1.6 x 10^{-6} M histamine. The contractile response varied with the histamine dose. In the kitten, the secretory response to 1.6 x 10^{-6} M histamine was similar to that in the ferret; 1.6 x 10^{-5} M histamine produced a further increase, which was not seen in the ferret. Changes in contractile activity and basal tension were much more profound than those seen in the ferret. In both animals, the similarity between the motility responses produced by cholinergic stimulation and pentagastrin was notable.

8665 ULTRASTRUCTURAL CHANGES IN MOUSE PARIETAL CELLS AFTER HIGH H^+ SECRETION. (Eng.)

Ito, S.; Schofield, G. C. (Harvard Medical Sch., Boston, MA). *Acta Physiol. Scand.* (Special Suppl.): 25-34; 1978.

Further elucidation of parietal cell ultrastructural changes found during different secretory stages, particularly when acid secretion was stopped, were studied. Perfused stomachs of anesthetized mice were monitored for acid secretion and then fixed at known periods of secretory activity and examined ultrastructurally. The characteristic morphology of active and of nonsecreting parietal cells was confirmed and some intermediate stages were observed. In histamine- and carbachol-stimulated parietal cells, taken from mice secreting as much as 1 μEq/g body weight/15 min at the peak period of secretion, the tubulovesicular compartment was greatly or completely depleted, and there was a great increase in the number and length of microvilli, which tended to occlude the luminal space of the canaliculi. In contrast to previous observations, this study suggests that the lumen of the gastric gland and the intracellular canaliculi are separate compartments. Observations in cat parietal cells, which showed an intracellular canaliculus with an open lumen, a canaliculus containing a section of a gastric spirillum, and lysosomal bodies containing spirilla, supported the internalization of the intracellular canaliculi. In mouse parietal cells recovering from high secretory activity, the lumen of the canaliculus appeared distended. Although elements of the tubulovesicular system came into close approximation with the plasma membrane, there was no evidence that there was any direct continuity between these two membrane compartments. Numerous small multivesicular bodies as well as lysosomes were apparent. When the parietal cells were returning to an inactive state, the microvilli seemed to lose some of their rigidity and were often pleomorphic or bulbous in shape. In some of these microvilli, tubular membranes were invaginated into the microvillar core. Concentric membrane profiles were present in the cytoplasm of recovering parietal cells. Associated with these concentric profiles were flattened vesicles and coated vesicles, the latter of which were either joined to the plasma membrane or free in the cytoplasm. In some cells, the cytoplasm contained clear, rounded or elongated bodies surrounded by two layers of closely apposed membranes. It is suggested that these morphological features and other processes that may not be apparent by current tissue preparation techniques are involved in the movement of membrane to and from the tubulovesicular compartment and the plasma membrane.

8666 THE ROLE OF ASPIRIN IN GASTRIC ULCERATION: SOME FACTORS INVOLVED IN THE DEVELOPMENT OF GASTRIC MUCOSAL DAMAGE INDUCED BY ASPIRIN IN RATS EXPOSED TO VARIOUS STRESS CONDITIONS. (Eng.)

Rainsford, K. D. (Univ. Tasmania Medical Sch., G.P.O. Box 252C Hobart, Tasmania, Australia). *Am. J. Dig. Dis.* 23(6):521-530; 1978.

The development of gastric mucosal damage induced by aspirin was studied in hooded rats stressed by physical (cold) and disease (adjuvant-induced arthritis, acute pain, inflammation) conditions to establish whether these stress states increase the susceptibility of gastric mucosa to aspirin damage. To elucidate the mechanisms involved in the physical stress plus aspirin interaction, a variety of pharmacological agents was also studied. Gastric irritation was measured 2 hr after the p.o. administration of aspirin (100-250 mg/kg) in a single dose or once daily doses for up to 10 days. Physical stress increased the sensitivity of the gastric mucosa to aspirin damage (there were 2.7 ± 1.0 lesions found in male rats treated with as-rin alone and 24.8 ± 9.5 lesions found in such ts with aspirin plus cold-stress treatment 0.05). No similar increases were noted in sease-stressed animals. Pharmacological inhibitors/antagonists of stress-mediated stomach ulration including atropine methyl nitrate (5-10 /kg, p.o.), bilateral vagotomy, phentolamine mg/kg, i.p.), propranolol (5 mg/kg, i.p.), metypone (250 µg/kg, i.m. for 4 days), metiamide (3 /kg, i.p.), cimetidine (5-40 mg/kg, i.p. or 40 /kg, p.o.), prostaglandins (PG) E_1 (2 mg/kg, i.p.), E_2 (5 mg/kg, i.p.), and 15(R),15-methyl PGE_2 (50 µg/ , i.p.) were studied. Use of the anticholinergic ent, atropine methyl nitrate (ED_{50}, 5 mg/kg folwing 200 mg/kg aspirin to stressed rats), bilaral vagotomy, or combined treatment with α- and -adrenergic blockers were effective in reducing e gastric mucosal irritation induced by aspirin us cold stress. The antisecretory agents prented the effects of aspirin plus cold stress, ostaglandins allowing no lesion formation at l. Levels of corticosterone in the blood and e distribution and metabolism of ^{14}C-labeled spirin in stressed and nonstressed rats were asured; as no differences in mucosal uptake of C-aspirin were observed, accelerated uptake of e drug was eliminated as a factor in the develment of gastric ulceration. The results show major involvement of the parasympathetic-vagal, mpathetic, and histamine-producing systems, but ot the adrenocortical axis, in the development of astric mucosal damage induced by aspirin plus hysical stress.

667 THE EFFECT OF BETA-ADRENERGIC AND CHOLINERGIC BLOCKADE ON THE CIRCADIAN RHYTHM OF ASTRINS IN SERUM.

(Eng.) Christensen, K. C.; tadil, F.; Malmstrom, J.; Rehfeld, J. F. (Rigsospitalet, 2100 Copenhagen, Denmark). *Scand. J. astroenterol.* 13(3):263-272; 1978.

tudies were carried out in 15 healthy subjects to etermine whether different gastrin components in he serum show circadian rhythms, and if so, whether eta-adrenergic and cholinergic blockade affect the erum concentration of gastrins. The subjects were nvestigated during p.o. treatment with the betadrenergic blocking agent propranolol (20 mg), the nticholinergic drug glycopyrron (1 mg), both rugs, or neither drug. Gastrin concentrations ere measured with an antiserum that measures all our main gastrin components in serum, and with a astrin-17-specific antiserum. A circadian rhythm as observed with both antisera. The total serum mmunoreactivity increased from 39 ± 3 pg/ml at 800 hr to a peak of 77 ± 7 pg/ml at 2300 hr, folowed by a nadir of 38 ± 2 pg/ml at 0400 hr. The ircadian rhythm was maintained during administraion of both drugs, but the concentrations of comonent III (gastrin-17) were reduced by beta-adrenrgic blockade (from 733 ± 71 to 599 ± 28 pg/ml/ r, p=0.05), while treatment with glycopyrron inreased the concentrations of the other gastrin omponents (from 490 ± 63 to 647 ± 57 pg/ml/hr, =0.01). The inhibition of gastric acid secretion y anticholinergics is presumably due to an action on the parietal cells; according to this study, the inhibition is connected by an increased gastrin stimulus. Beta-adrenergic blockade, however, seems to reduce the gastrin stimulus and might be of therapeutic interest in duodenal ulcer disease.

8668 THE INFLUENCE OF ATROPINE ON INSULIN- AND 2-DEOXY-D-GLUCOSE (2-DG)-INDUCED GASTRIN RELEASE IN DOGS.

(Eng.) Ornsholt, J.; Brandsborg, O.; Brandsborg, M.; Lovgreen, N. A.; Amdrup, E. (Kommunehospitalet, DK-8000 Arhus C, Denmark). *J. Surg. Res.* 23(4):246-250; 1977.

To evaluate whether parietal cells and gastrin cells differ in sensitivity to atropine, the influence of this drug on insulin- and 2-deoxy-D-glucose (2-DG)-induced gastric acid secretion and gastrin release was studied in gastric fistula dogs. 2-DG (200 mg/kg, i.v.) caused a pronounced rise in acid secretion within the first 15 min after injection ($p<0.05$), as compared with the basal level. Insulin (0.25 U/kg, i.v.) produced a marked increase in acid secretion over the basal level, with a peak output in the 30- to 45-min period. Insulin also produced increases in the serum gastrin level, which were significantly elevated above the basal level from 30 to 90 min after injection ($p<0.05$). The mean gastrin concentration stimulated by 2-DG showed an immediate rise to a peak value 15 min after the injection ($p<0.01$). Then a marked decrease occurred, reaching basal concentration at 45 min. Atropine pretreatment (0.05 mg/kg, s.c.) caused an almost complete block of insulin-induced acid secretion during the first three 15-min periods, but a weak secretion was recorded about 60 min after the injection, followed by a gradual decrease to the basal level at 120 min. Atropine initially blocked 2-DG-stimulated acid output, but thereafter a constant increase in acid output was observed. The acid output between 105 and 135 min was significantly higher than the basal secretion ($p<0.05$). Atropine in doses of 0.05 to 0.2 mg/kg had no effect on 2-DG- or insulin-stimulated gastrin release. Gastrin release during hypoglycemia in the dog might be cholinergic but resistant to atropine doses that are sufficient to block acid secretion.

8669 THE INHIBITION OF GASTRIN PRODUCTION BY CALCITONIN IN THE AGED.

(Ita.) Passeri, M.; Palummeri, E.; Soncini, G.; Monica, C.; Ferretti, P. G.; Galvagni, R. (Cattedra di Gerontologia e Geriatria dell'Universita degli Studi di Parma, Parma, Italy). *G. Clin. Med.* 58(9/10):321-338; 1977.

The effect of calcitonin on gastrin production in the aged was studied. A group of volunteers (average age 72 ± 3 yr) with no apparent gastrointestinal disorders was given pig calcitonin or salmon calcitonin (24 mg/kg or 20 µg, resp., i.v.) prior to a high-protein (9.5 g/250 ml) meal. The same patients served as controls when they received only the high-protein meal in a test carried out 72 hr prior to the calcitonin experiment. Blood samples taken during both studies were analyzed for calcium, gastrin, and insulin levels. In the 16 patients treated with pig calcitonin, the gastrin response peaked at 15 min after the meal at 130% of its basal value, whereas it reached 190% of its basal value at this time when calcitonin was not given first. At 90 min after the meal, the calcium level was approximately 9.5 mg/100 ml in the controls but about 9.2 mg/100 ml in the treated group. The insulin level was approximately 12 μU/ml 30 min after the meal in the controls but about 8 μU/ml when in the treated group. For those treated with salmon calcitonin, the gastrin values reached 160% of base value in the controls but only about 110% of base value in the treated group 20 min after the meal. The calcium level 10 min after the meal was approximately 10.1 mg/100 ml in the controls and about 9.8 mg/100 ml in the treated group. The insulin level was about 19 μU/ml 20 min after the meal in the controls but about 7 μU/ml in the treated group. The authors state that the results were statistically significant between the control and treated group for both pig and salmon calcitonin 20 and 30 min after the meal. It is suggested these effects might be important in postprandial regulation of calcemia, in the nourishment of bone, and in senile osteoporosis.

8670 INHIBITION BY SOMATOSTATIN (GROWTH-HORMONE RELEASE-INHIBITING HORMONE, GH-RIH) OF GASTRIC ACID AND PEPSIN AND G-CELL RELEASE OF GASTRIN.

(Eng.) Barros D'Sa, A. A. J.; Bloom, S. R.; Baron, J. H. (Singleton Hosp., Swansea, Wales). *Gut* 19(4):315-320; 1978.

The effects of somatostatin (cyclic growth hormone release-inhibiting hormone, GH-RIH) on gastric acid, gastrin, and pepsin secretion in response to insulin hypoglycemia, a meat meal histamine, and pentagastrin were studied in dogs with gastric fistulae. During experiments in which secretion was stimulated with histamine and pentagastrin, somatostatin was infused in the second hour of a 3-hr infusion of submaximal doses of histamine acid phosphate (0.5 μg/kg/min) and pentagastrin (1 μg/kg/hr). In the insulin experiments, insulin (0.2 U/kg) was given as a single i.v. injection, and somatostatin (5 or 8 μg/kg/hr) was infused for 30 min before and at 90-120 min after the insulin injection. During meal-stimulated experiments, somatostatin was given i.v. in the first 2 hr of a 3-hr experiment. In insulin-stimulated secretion experiments, the mean gastrin increment was inhibited by 70% after the lower dose and by 86% after the higher dose of somatostatin, almost identical with the inhibition of insulin-stimulated acid output of 74% and 85%, resp., after these doses. After a meal, inhibition of acid output was greater with increasing doses of somatostatin. At the lowest somatostatin dose (0.5 μg/kg/hr), there was a rebound in secretion after the somatostatin infusion was stopped, with the acid output exceeding control levels. During the 2-hr infusion with 1 μg/kg/hr somatostatin, gastric acid secretion was totally inhibited in every dog, with some return of secretion after the infusion was terminated. Acid secretion was completely inhibited throughout the 3 hr with the other four doses (2, 4, 8, and 16 μg/kg/hr). Meal-stimulated gastrin inhibition was also dose-dependent. Pepsin outputs after somatostatin were inhibited less than were acid outputs. Histamine-stimulated acid secretion was inhibited by somatostatin, and pentagastrin-stimulated acid output decreased immediately and rapidly after somatostatin was infused. Acid and pepsin outputs stimulated by pentagastrin were reduced by 94% and 76%, resp., after somatostatin. Basal plasma gastrin levels were not affected by histamine or pentagastrin infusions. During somatostatin infusion, the basal plasma levels were depressed, with some recovery after somatostatin infusions were stopped. These studies show that somatostatin inhibits the release of acid, pepsin, and gastrin from parietal, chief, and G-cells in response to a meal; of acid and gastrin in response to insulin; and of acid and pepsin in response to pentagastrin and histamine.

8671 INHIBITION OF GASTRIC ACID SECRETION IN DOGS BY A NEW SYMPATHOMIMETIC DRUG.

(Eng.) Gottrup, F.; Ornsholt, J. (Dept. Anatomy, Univ. Arhus, 8000 Arhus C, Denmark). *Scand. J. Gastroenterol.* 13(3):337-343; 1978.

The inhibitory effect of a new β_2-agonist, salmefamol, on pentagastrin-induced acid secretion was studied in conscious gastric-fistula dogs. Maximal pentagastrin-induced acid secretion was significantly reduced at i.v. doses of 0.1, 0.2, 0.4, and 0.8 μg/kg/min salmefamol. The inhibition was 43 ± 8% for the lowest dose (0.05 μg/kg/min) and 89 ± 4% for the highest dose (0.8 μg/kg/min). Inhibition occurred within 15 and 30 min, and the effect was maximal after 45 min. A dose-related decrease in the titratable acidity and volume was demonstrated. The maximal decrease was 34 ± 3% ($p<0.05$) and 83 ± 5% ($p<0.05$), resp. Salmefamol caused an increase in the pulse rate of 34 ± 5% (at the lowest dose) to 96 ± 22% (at the highest dose). Propranolol (0.2 mg/kg, i.v.) prevented the inhibition of acid output as well as the increase in pulse rate. Practolol (0.4 and 1.0 mg/kg, i.v.) had no effect on the inhibition of acid secretion but prevented the increase in pulse rate. Dose-response experiments with 0.25-8.00 μg/kg/hr pentagastrin and salmefamol at 0.1 μg/kg/min showed a decrease in the calculated maximal response and an unchanged half maximal acid response. It is concluded that salmefamol strongly inhibits pentagastrin-induced acid output in the dog, and that the inhibition follows noncompetitive kinetics. The mechanism of gastric secretion probably involves a β_2-receptor.

8672 BACTERIAL FLORA AND NITRITE PRODUCTION IN THE STOMACH AFTER GASTROENTEROSTOMY. EXPERIMENTAL ASPECTS OF THE PATHOGENESIS OF CARCINOMA IN THE OPERATED STOMACH.

(Ger.) Schlag, P.; Wonka W.; Meyer, H.; Feyerabend, G.; Merkle, P. (Abteilun fur Allgemeine Chirurgie des Departments fur Chirurgie, Universitat Ulm, Steinhovelstr. 9, D-7900

Ulm, W. Germany). *Langenbecks Arch. Chir.* 344(2): 109-114; 1977.

The effect of gastroenterostomy without entero-anastomosis, of gastroenterostomy with Roux-en-Y anastomosis, and of gastrotomy on the nitrite-decomposing bacteria of the stomach was studied in specific pathogen-free male Wistar rats to investigate the increased gastric cancer risk following gastric surgery. Gastroenterostomy without enteroanastomosis caused a marked increase in the proportion of the nitrite-decomposing bacteria (*Escherichia coli, Lactobacillus acidophilus, Peptostreptococcus productus,* and *Eubacterium contortum*), and, accordingly, a sixfold increase in the nitrite concentration in the gastric juice 35 weeks after operation. No significant change was seen in the proportion of the nitrite-decomposing bacteria or in the nitrite level of the gastric juice of the rats that underwent gastroenterostomy with Roux-en-Y anastomosis compared with the gastrotomied (control) rats. Increased nitrite concentration in the gastric juice may lead to an enhanced production of carcinogenic nitrosamines.

8673 EFFECT OF BILE ON LYSOSOMAL STABILITY IN THE MUCOSA OF THE CANINE GASTRIC ANTRUM. (Eng.) Waldron-Edward, D.; Boutros, M. I. R.; Himal, H. S. (Dept. Experimental Surgery, McGill Univ., 740 McGregor, Montreal, Quebec H3A 1A4, Canada). *Gastroenterology* 73(5):980-984; 1977.

The activities of bound and free hydrolases and the response of the membranes to hypoosmotic (distilled water, 4 C, 240 min) and mechanical (tissue grinder) stress were studied in explanted canine antral mucosa to investigate the role of bile reflux in ulcerogenesis. Tissue and bile were obtained from the same mongrel dogs and the explanted mucosa was treated with bile or bile and then acid and fractionated to obtain the lysosome-rich pellet. The particulate enzymes, acid phosphatase (AcP), cathepsin D (CD), β-galactosidase (βGAL), α-galactosidase (α-GAL), β-*N*-galactosaminidase (β-*N*-GAL), β-*N*-glucosaminidase (β-*N*-GLU), and α-fucosidase (α-FUC), varied considerably in the stability of their binding to subcellular organelles when the tissue had been treated with acid (120 mEq HCl)-saline (40 mEq NaCl) for 60 min: α-FUC and β-*N*-GAL activities remained tightly bound after hypoosmotic shock or mechanical stress, whereas about three times as much β-GAL and β-*N*-GLU activities (percentage of initially bound activity) were released. When tissue was treated with bile for 60 min, very little enzyme activity was lost from membranes during subsequent treatments; however, hypoosmotic shock doubled the release of CD into the soluble fraction ($p<0.001$) compared with nontreated mucosa subjected only to acid-saline. Similarly, soluble protein increased by 75% ($p<0.001$). The pellets from tissue treated first with bile (30 min) and then acid-saline (15 or 30 min) were quite fragile to hypoosmotic shock, the fragility increasing with time of exposure to acid-saline; the percentage of previously bound activity lost was significant in every case after the 30-min acid-saline treatment ($p<0.01$ for β-*N*-GLU and $p<0.001$ for AcP, CD, β-GAL, α-GAL, β-*N*-GAL, and α-FUC). However, this tissue yielded pellets that were markedly resistant to mechanical stress and only AcP, β-*N*-GLU, β-*N*-GAL, and α-FUC activities were released in significant ($p<0.001$) amounts. The total free plus labilizable activity of most of the acid hydrolases of the mucin-cleared, nuclei-free homogenates from the insulted mucosa decreased slightly from control levels, with a marked increase in protein level and decrease in enzyme specific activity in this fraction. The increased levels of free enzyme appeared in the supernatant fraction, reaching a significant level ($p<0.01$ or 0.05) in the bile-then acid-treated samples. It is concluded that, while bile alone has little direct effect on the membrane binding or activation of most acid hydrolases, it facilitates the influx of H^+, thus releasing the acid hydrolases into an active acidic environment and exposing the entire mucosal cell structure to abnormal biodegradation or autolysis.

SECRETION AND METABOLISM

Pancreas

3699 COMPARISON OF TWO METHODS FOR DETERMINING THE DOSE-EFFECT RELATIONSHIPS BETWEEN CHOLECYSTOKININ AND EXOCRINE PANCREATIC FUNCTION IN THE DOG. (Ger.) Singer, M. V.; Dermol, P.; Mendes de Oliveira, J. P.; Sarles, H. (Unite de Recherches de Pathologie Digestive, INSERM, U 31, 46, chemin de la Gaye, F-13009 Marseille, France). *Z. Gastroenterol.* 16(2):95-100; 1978.

Dose-response curves to cholecystokinin (CCK) for pancreatic flow rate, bicarbonate output, and protein output were determined by two different techniques in three conscious dogs with gastric and duodenal Thomas fistulas. With the continuous technique (CT), the CCK dose was doubled each 45 min (3, 6, 12, and 24 Crick-Harper-Raper U/kg/hr). With the single-dose technique (SDT), only one of the above doses of CCK was administered on each test day. CCK was administered together with secretin (1 U/kg/hr, i.v.). The dose-response curves for pancreatic flow and bicarbonate output did not differ with the two techniques. At low CCK doses (3, 6, or 12 U/kg/hr), there was no difference between the two methods concerning the protein output. At the highest CCK dose (24 U/kg/hr), the maximum protein output was reached using the SDT; this output was significantly higher than that obtained with the CT ($p<0.01$). Consequently, the SDT is the method of choice for the determination of the maximum protein output, while the CT is sufficient for the determination of dose-effect relationships between submaximal CCK doses and protein output.

8700 EFFECTS OF HYPERTONIC GLUCOSE AND AMINO ACID INFUSIONS ON PANCREATIC EXOCRINE FUNCTION. (Eng.) Saito, Y.; Tokutake, K.; Matsuno, S.; Noto, N.; Honda, T.; Sato, T. (Tohoku Univ. Sch. Medicine, Sendai 980, Japan). *Tohoku J. Exp. Med.* 124(2):99-115; 1978.

The inhibiting effects of an i.v. infusion of 20% glucose, 30% glucose, 12% amino acids, or 20% mannitol (200 ml/hr for 1 hr or more) on pancreatic exocrine function were studied in mongrel dogs with chronic gastric and pancreatic fistulae. The effects of glucagon injected i.v. at intervals of 50 min in increasing doses of 2, 8, 16, and 32 μg/kg were measured (glucagon loading test). Basal stimulation by secretin and pancreozymin (continuous i.v. infusion of 0.025 U/kg/min in conscious dogs and 0.05 U/kg/min in anesthetized dogs) was also measured and showed a plateau in the volume of secreted pancreatic juice at 50-60 min after the start of infusion. Satisfactory results were obtained only with conscious dogs except in the measurement of immunoreactive glucagon (IRG). Infusion with 20% glucose, 30% glucose, or 12% amino acids for 1 hr significantly decreased both volume of pancreatic juice ($p<0.001$, $p<0.01$, $p<0.001$, resp.) and amylase output ($p<0.01$ for all 3 solutions) compared with preloading levels. In addition, both 30% glucose and 12% amino acids were more potent inhibitors than was 20% glucose ($p<0.05$ for both solutions). No changes in bicarbonate concentration were noted. The infusion of 20% mannitol for 2 hr produced an initial drop in the volume of pancreatic juice and in amylase output compared with preloading levels (both decreases were maximal at 10 min, $p<0.02$ and $p<0.05$, resp.), but at 50 min, both levels reverted to initial levels despite continuing infusion. When the 12% amino acid infusion was continued for 2 hr, however, both levels remained suppressed throughout the infusion. These differences in pancreatic response to 20% mannitol and to solutions having osmotic pressures equal to or greater than 20% mannitol showed that osmotic pressure does not exert a significant influence on the inhibitory effects of the test solutions. The 20% and 30% glucose infusions elevated blood sugar levels to average values of 261 and 367 mg/100 ml, resp. Increases in the levels of immunoreactive insulin (IRI) were produced by both glucose infusions and by the 12% amino acid infusion (levels never exceeded 73 μl/ml). There was an increase in the level of IRG following the 12% amino acid infusion but no trend of increase following either glucose infusion. Infused glucagon produced transitory inhibition of pancreatic juice secretion and amylase excretion, with the reduced values tending to return to initial levels 30 min after each injection. The greatest inhibition of pancreatic exocrine secretion in these experiments was produced by the amino acid infusion; IRI and IRG levels rose markedly. The stimulated glucagon release contributed to the suppression of pancreatic secretion. The infusion rate used in these studies was several times greater than the rate used clinically for hyperalimentation in adults with acute pancreatitis, but the solution concentrations are those used routinely. The marked suppression of pancreatic secretion observed tends to support the hypothesis that hyperalimentation with hypertonic glucose and amino acids is of value in the treatment of acute pancreatitis.

8701 THE EFFECT OF PROLACTIN ON CANINE PANCREATIC SECRETION: IMPLICATIONS ON THE PATHOGENESIS OF THE PANCREATITIS OF PREGNANCY.

(Eng.) Rosenberg, V.; Dreiling, D. A. (Mt. Sinai Sch. Medicine, City Univ. New York, 100th St. and Fifth Ave., New York, NY 10029). *Am. J. Gastroenterol.* 67(4):354-361; 1977.

The effect of the acute administration of prolactin on canine pancreatic secretion was studied to investigate the possibility that the pancreatitis of pregnancy may have a hormonal etiology. Pancreatic secretion was studied in 10-min samplings for 1 hr after the continuous i.v. pump infusion of secretin (0.3 U/kg/min) plus cholecystokinin-pancreozymin (CCK-PZ, 0.05 U/kg/min). The study was continued for an additional 3 hr after bolus administration of 2 mg prolactin. The average hourly volume, bicarbonate, and protein outputs during infusion of secretin and CCK-PZ were 104.5 ml, 13.8 mEq, and 1,298 mg, resp. The average hourly concentrations of bicarbonate and protein during this time were 132 mEq/l and 12.4 mg/ml. The average values during the first hour after prolactin injection were 84.7 ml, 9.3 mEq, and 1,088 mg for volume, bicarbonate, and protein output, resp., and 109 mEq/l and 12.8 mg/ml for bicarbonate and protein concentration, resp. During the second hour, these levels were 100.4 ml, 10.1 mEq, 799 mg, 101 mEq/l, and 7.9 mg/ml, resp. At hour 3, the levels were 101.6 ml, 9.7 mEq, 790 mg, 95 mEq/l, and 7.7 mg/ml, resp. These results show that prolactin diminishes the pancreatic response to continuous secretin plus CCK-PZ infusion. Protein enzyme concentration was unaltered, so that protein output was maintained. These alterations produce a low-flow enzyme-concentrated juice that would afford the possibility of small duct blockade by protein plug, thus explaining the pancreatitis of pregnancy.

8702 EFFECT OF SOMATOSTATIN ON BASAL AND STIMULATED PANCREATIC SECRETION IN THE RAT.

(Eng.) Folsch, U. R.; Lankisch, P. G.; Creutzfeldt, W. (Dept. Medicine, Univ. Gottingen, Gottingen, W. Germany). *Digestion* 17(3):194-203; 1978.

The response to somatostatin of basal and cholecystokinin (CCK)- and secretin-stimulated pancreatic secretion was studied in anesthetized male Wistar rats. The i.v. infusion or bolus injection of somatostatin was always preceded by at least 30 min of 0.15 M NaCl infusion. Dose schedules were (1) somatostatin, 100 μg/hr by infusion or a bolus injection of 50 μg/100 g, (2) 3 Ivy dog U (IU) CCK-PZ/100 g/hr alone or combined with 50 or 100 μg/100 g/hr somatostatin, and (3) 0.8 clinical U (CU) secretin/100 g/hr for 60 min followed by the same dose of secretin either alone or combined with 50, 100, or 200 μg/100 g/hr somatostatin. The basal secretion of amylase was markedly inhibited by the 100 μg/100 g/hr somatostatin dose; however, the bolus injection of 50 μg/100 g somatostatin produced a fourfold increase in amylase secretion for 10-20 min followed by a return to the basal level. No changes in volume of secretion were observed. The combination of 3 IU/100 g/hr of CCK with 100 μg/100 g/hr somatostat caused strong inhibition of amylase and trypsin secretion. The enzyme secretion increased immediately after termination of the somatostatin infusion, reflecting the short (3 min) half-life of CCK and demonstrating the reversibility of the inhibitory action of somatostatin. The CCK-stimulated volume output was markedly reduced by an infusion of 100 μg/100 g/hr somatostatin. The inhibition continued after the termination of the somatostatin infusion. No significant changes in the pattern or magnitude of secretin-stimulated pancreatic volume and bicarbonate secretion were observed. In these experiments, somatostatin did not influence secretin-stimulated bicarbonate concentration or rate of secretion but did influence the basal secretion of amylase. The CCK-stimulated enzyme and volume secretion were inhibited by somatostatin.

8703 SULPHATE METABOLISM IN THE EXOCRINE PANCREAS. II. THE PRODUCTION OF SULPHATED MACROMOLECULES BY THE MOUSE EXOCRINE PANCREAS.

(Eng.) Berg, N. B. (State Univ. New York, Upstate Medical Center, Syracuse, NY 13210). *J. Cell Sci.* 31:199-211; 1978.

The types of sulfated macromolecules, in particular, proteins, proteoglycans, and lipids, produced by the exocrine mouse pancreas were investigated in pancreatic tissue taken from male Swiss mice. The behavior of sulfated macromolecules (labeled with ^{35}S-sulfate) and secretory proteins (labeled with ^{3}H-leucine) was compared. In the presence of 5 x 10^{-4} M cycloheximide, a strong inhibitor of protein synthesis, tissue uptake of radioleucine was reduced about 95% of control valu during the first 30 min of incubation. A similar reduction in radiosulfate utilization was not evident until 4 hr of incubation, when an apparent intracellular pool of protein needed for the production of sulfated macromolecules was exhausted. Pilocarpine-induced secretion of macromolecules was studied by radioassay. In the presence of pilocarpine nitrate (5 x 10^{-7} M), both radioleucin and radiosulfate-labeled secretory material attain a level of 40% net secretion at 90 min postpulse. Material labeled with inorganic sulfate consistent appeared in the chase medium 10-15 min prior to the secretory proteins, reflecting a shorter intra cellular transport route taken by the sulfated material. In the next 90 min, the secretory proteins accumulated to nearly 70% net secretion whil sulfated material accumulation reached only 50% net secretion. These differences in secretion sho that leucine and inorganic sulfates are used for the production of different macromolecular species and indicate that the sulfated material is not secretory protein. The radioactivity of lipid and proteoglycan fractions prepared from pancreatic tissue 4 hr after i.p. injection of radiosulfate demonstrated that both sulfated proteoglycans and sulfolipids were produced in the pancreas. The experiments demonstrate that pancreatic acinar cells can utilize inorganic sulfate for the sulfination of proteoglycans and lipids but not of proteins.

8704 ACUTE HEMORRHAGIC PANCREATIC NECROSIS IN MICE: BILE ACIDS IN GALLBLADDER BILE, SERUM AND PANCREAS. (Eng.) Yousef, I. M.; Rao, K. N.; Lombardi, B.; Fisher, M. M. (Dept. Medicine, Univ. Toronto, Toronto, Ontario M5S 1A8, Canada). *Acta Hepatogastroenterol.* 25(1):55-61; 1978.

Because bile acids are implicated in the pathogenesis of acute hemorrhagic pancreatic necrosis with fat necrosis, the bile acid composition of the pancreas, serum, and gallbladder bile of mice was studied. Mice were fed (a) a choline-deficient ethionine-supplemented (CDE) diet (0.5% DL-ethionine), (b) a choline-supplemented diet (CS), (c) a choline-deficient (CD) diet, or (d) a normal control diet for 1, 2, or 3 days. In addition, bile acids were analyzed in the pancreas, gallbladder, and serum of animals with pancreatic necrosis. Moderate degrees of compression atrophy of the mucosa and wall of the gallbladder were present in 2 of 12 mice fed the CS diet, in 5 of 14 mice fed the CD diet, and in 8 of 16 fed the CDE diet; severe degrees of atrophy were present in 5 of 12 fed the CS diet, in 9 of 14 fed the CD diet, and in 8 of 16 fed the CDE diet. The concentration of total bile acids in gallbladder bile of mice fed the CDE diet was significantly lower than that in mice fed the other diets ($p<0.05$). The amount of total bile acids in the gallbladders of mice fed the experimental diets was two- to fourfold greater than that in the controls. The bile acid composition of the bile was similar in mice on the normal and choline-supplemented diets. Choline deficiency reduced the relative amount of cholic acid, while ethionine supplementation increased the relative amount of the dihydroxy unsaturated cholanic acid. Plasma bile acid composition was affected by the different diets in a manner similar to that in the bile. However, the total bile acid concentration in the plasma of mice fed the CDE diet was significantly lower than that in the plasma of mice fed the other diets ($p<0.05$). In the pancreas, cholic acid accounted for only about 25% of the bile acids extracted, and no muricholic acids were found. Total bile acid concentration and bile acid composition were not affected by any of the diets. However, the amount of total bile acids per pancreas was significantly greater in mice fed the CDE diet ($p<0.05$), due to a larger pancreas weight in these animals, than that in the mice fed the other diets. Bile acids apparently do not initiate or participate in the extensive cellular damage preceding and accompanying the onset of acute hemorrhagic pancreatic necrosis with fat necrosis in mice fed a CDE diet.

8705 SPECIES SPECIFICITY AND OTHER ASPECTS OF CHYMOTRYPSIN INHIBITION BY PLASMA. (Eng.) Wolgemuth, R. L.; Hanson, K. M. (Ohio State Univ. Coll. Medicine, 333 W. Tenth Ave., Columbus, OH 43210). *Digestion* 16(1/2):96-107; 1977.

8706 HUMAN PANCREATIC CATIONIC TRYPSIN AS A POSSIBLE MEDIATOR OF PANCREATIC SHOCK AS INFERRED FROM A STUDY OF ITS INTERACTION WITH SERUM AND α_2-MACROGLOBULIN. (Eng.) Aubry, M.; Travis, J.; Bieth, J. SECRETION AND METABOLISM

Hepatobiliary Tract

8709 MICROSOMAL DRUG METABOLISM IN ACUTE AND CHRONIC GALACTOSAMINE INCUCED HEPATIC INJURIES. (Eng.) Shigeta, Y. (Sch. Medicine, Keio Univ., Tokyo, 160 Japan). *Gastroenterol. Jpn.* 12(6):435-445; 1977.

Female Wistar rats were given D-galactosamine (GalN) acutely (400 mg/kg body weight, i.p.) or chronically (250 mg/kg body weight daily for 7 months, i.p.) to determine its effects on the biochemical components and drug-metabolizing activities of the microsomal membrane. Acute or chronic GalN administration produced significant ($p<0.01$) increases in liver weight compared with controls. Hepatic triglyceride concentration was significantly ($p<0.001$) increased by acute but unaffected by chronic GalN administration. The microsomal protein content was unchanged in the acute study but was significantly ($p<0.01$) decreased in the chronic study. Both studies demonstrated significant ($p<0.05$) increases in microsomal phospholipid content, expressed per mg of microsomal protein. Acute GalN administration produced a significant decrease in the cytochrome P450 content whether expressed per mg of microsomal protein ($p<0.001$) or per unit of body weight ($p<0.01$). Chronic GalN administration produced a significant increase in cytochrome P450 content when expressed per mg of microsomal protein ($p<0.01$) or per unit of body weight ($p<0.001$). Cytochrome b5 content was significantly increased in the acute study ($p<0.001$-0.05). NADPH cytochrome C reductase activity was unchanged in either study. The *N*-demethylating activity for aminopyrine was significantly decreased in the acute study when expressed per mg of microsomal protein ($p<0.02$) or per g of liver ($p<0.001$). In the chronic study, it was significantly increased when expressed per unit of body weight ($p<0.05$). Both studies demonstrated marked reductions in microsomal glucose-6-phosphatase activity. Electron microscopy of chronically damaged livers showed relatively well-preserved intracellular organelles of hepatocytes and an apparent proliferation of mitochondria. The smooth endoplasmic reticulum showed focally accentuated hypertrophy with liposomes in the dilated tubules. The data indicate that, in acute liver injury, hepatic microsomal drug-metabolizing activity is impaired. In chronic injury, the decreased drug-metabolizing capacity per unit of liver may be compensated by the enlarged hepatic mass, resulting in normal or even enhanced drug-metabolizing activity when expressed per unit of body weight.

8710 SIGNIFICANCE OF ENDOTOXAEMIA IN EXPERIMENTAL "GALACTOSAMINE-HEPATITIS" IN THE RAT.

(Eng.) Grun, M.; Liehr, H.; Rasenack, U. (Medizinische Universitatsklinik, Josef-Schneider-Str. 2, 8700 Wurzburg, W. Germany). *Acta Hepatogastroenterol.* 23(2):64-81; 1976.

Normal, colectomized, and endotoxin-resistant rats were studied after the induction of hepatitis by an i.p. injection of GalN (1.0 g/kg) to determine whether endotoxins contribute significantly to the pathogenesis of galactosamine (GalN)-induced hepatitis. Endotoxemia was detected by the limulus gelation test (LGT) within 9 hr after GalN administration in the normal rats. Weak endotoxemia was present in only 25% of the colectomized animals and in none of the rats resistant to exogenous and endogenous endotoxins. Phagocytic capacity decreased significantly ($p<0.0001$) by 72 hr following GalN administration in the normal rats but not in colectomized or endotoxin-resistant rats. The development of other clinical symptoms of GalN-induced hepatitis, including pyrogen reaction, disseminated intravascular coagulation, arterial hypotension, and hypoglycemia, correlated significantly with the development of endotoxemia. Hyperbilirubinemia was present after GalN treatment only in the animals that did not undergo colectomy or procedures that made them endotoxin-resistant. Transaminase elevation was lower or normal in colectomized or endotoxin-resistant animals than in animals that did not undergo pretreatment. The results indicate that endotoxins contribute significantly to the pathogenesis of GalN-induced hepatitis and to its clinical symptoms.

8711 PROTECTIVE ACTIVITY OF WHITE PHOSPHORUS ON HEPATIC TOXICITY IN THE RAT. (Fre.)

Quilichini, R.; Bildet, J.; Saurel, J.; Gendre, P. (Laboratoire de pharmacologie, Universite de Bordeaux II, 24 rue Paul Broca, 33000 Bordeaux, France). *Rev. Fr. Gastroenterol.* (138):25-36; 1978.

The ability of small doses of white phosphorus (WP) to prevent or reverse CCl_4-induced (1 g/kg, i.p.) liver toxicity was studied in male Wistar rats. Simultaneously, one-third of the rats received i.p. injections of a 10^{-14} dilution of 7 CH WP, one-third received injections of 10^{-30} 15 CH WP, and one-third received physiological serum (controls). The levels of SGOT, SGPT, and serum lactate dehydrogenase (LDH) were measured for 4 days after the injection. Histological studies on the livers of sacrificed animals were performed by electron microscopy 2, 12, and 48 hr after injection and by light microscopy 3, 8, and 15 days after injection. At 48 hr, the SGOT, SGPT, and LDH levels were consistently lower in rats given the 10^{-14} dilution of WP, compared with the animals treated with the 10^{-30} dilution of WP and the controls; the postinjection curves of the levels of SGOT, SGPT, and LDH were almost identical in the latter two groups over the 4-day period. Electron microscopy revealed fewer changes in the hepatocytes, such as degeneration and vacuolization, and light microscopy showed fewer areas of necrosis in rats treated with WP compared to controls; the lower dose of WP appeared histologically more efficacious. In a second study, rats were injected with two doses/day i.p. of either 10^{-14} or 10^{-30} dilutions of WP or with physiological serum for 15 days. These injections were discontinued 2 days prior to CCl_4 injection (1 g/kg, i.p.). The levels of SGOT, SGPT, and serum LDH, in particular, were lower in rats treated with either WP dilution compared with controls; the 10^{-14} dilution of WP was more efficacious than the 10^{-30} one in lowering liver enzyme levels after CT intoxication. Again, histological studies showed less evidence of necrosis in WP-treated rats. It is concluded that very weak dilutions of WP have a preventative and curative action with respect to the hepatic toxicity of CCl_4 in the rat.

8712 BILIARY SPASMOLYTIC ACTION OF 3-(2,4,5-TRIETHOXYBENZOYL) PROPIONIC ACID (AA-149) IN DOGS.

(Eng.) Satoh, H.; Maki, Y.; Kanno, M. (Medicinal Res. Lab., Central Res. Div., Takeda Chemical Industries, Ltd., Osaka 532, Japan). *Eur. J. Pharmacol.* 48(3):309-317; 1978.

A study of 3-(2,4,5-triethoxybenzoyl)propionic acid (AA-149) was undertaken to clarify its mode of action on the motor function of the biliary tract in anesthetized dogs relative to autonomic drugs, gastrointestinal hormone, morphine, and taurocholate. The resistance of the choledochoduodenal junction (CDJ), gallbladder pressure (GP), bile flow, biliary ductal pressure, and blood pressure were recorded simultaneously. Doses included i.v. injections of carbachol (0.5 µg/kg), morphine (5 µg/kg), atropine (0.1-1 mg/kg), isoproterenol (1 µg/kg), propranolol (2-10 mg/kg), cholecystokinin (CCK, 0.1-1 mg/kg), and taurocholate (10 mg/kg). AA-149 was administered intrajejunally or i.v. at doses of 2, 5, or 10 mg/kg. At all dose levels and by both means of administration, AA-149 produced a dose-dependent reduction in the resistance of the CDJ and in GP along with a dose-dependent increase in bile flow. Like CCK, AA-149 decreased biliary ductal pressure while increasing the bile flow in dogs with ligation of the cystic duct of the gallbladder. Taurocholate produced increases in both biliary ductal pressure and bile flow. The spasmic response of the CDJ to morphine was not consistently depressed by atropine, but it was depressed strongly by AA-149. The effects of AA-149 were not influenced by pretreatment with atropine, phentolamine, or propranolol. The findings suggest that AA-149 relaxes the biliary tract (relaxation of the sphincter of Oddi) and depresses morphine-induced spasm by a mechanism of action different from that of atropine. The relaxing effect of AA-149 on biliary smooth muscle is not mediated by cholinergic or adrenergic mechanisms. It is likely that AA-149 acts directly on biliary smooth muscle rather than acting indirectly through release of CCK. The authors conclude that AA-149 is a novel compound with choleretic activity and with a strong spasmolytic activity on the biliary tract and that it acts by a mechanism different from those of anticholinergic and sympathomimetic agents.

8713 THE INFLUENCE OF β-SITOSTEROL ON BILIARY CHOLESTEROL SATURATION AND BILE ACID KINETICS IN MAN. (Eng.) Begemann, F.; Bandomer, G.; Herget, H. J. (I. Medizinische Klinik der Universitat Hamburg, Martinistr. 52, D-2000 Hamburg 20, W. Germany). *Scand. J. Gastroenterol.* 13(1):57-63; 1978.

To further investigate β-sitosterol as a possible agent for the treatment of cholelithiasis, its effect on cholesterol saturation of human bile and on bile acid kinetics was studied in 10 patients without hepatic or intestinal disease, 6 of whom had mild to moderate hyperlipemia. The administration of β-sitosterol (12 g/day, p.o.) for 6-8 weeks resulted in a mean decrease of 11% in serum cholesterol level ($p<0.02$) and of 12% in biliary cholesterol saturation ($p<0.05$); the latter effect was due to a change in the relative amounts of biliary lipids (lower cholesterol levels and higher bile acid values), whereas phospholipids varied insignificantly. Individual long-term observations revealed a sustained reduction or a further decrease in the lithogenic index in three patients, while in a fourth, who presented originally with undersaturated bile, an initial slight decrease of the lithogenic index was no longer detectable after 20 months. Significant changes in bile acid kinetics were not detected. The results lend support for further investigations of sitosterol as a possible adjunct therapy in cholelithiasis.

8714 EFFECT OF SPIRONOLACTONE ON BILE FORMATION AND LIVER MICROSOMAL ENZYMIC ACTIVITIES IN THE RAT. (Fre.) Miguet, J. P.; Mavier, P.; Arondel, J.; Preaux, A. M.; Dhumeaux, D. (Hopital Henri-Mondor, F 94010 Creteil, France). *Gastroenterol. Clin. Biol.* 1(12):1007-1013; 1977.

To elucidate the mechanism of the diuretic spironolactone on drug metabolism, the effect on bile formation, liver microsomal oxidation, and conjugation of drugs was studied in rats. Male Sprague-Dawley rats were given 15 mg/100 g spironolactone p.o. for 4 days and then fasted for 1 day without water restriction. After catheterization of the bile duct, bile was collected every 10 min for 30 min. The 14 treated rats had a 40% increase in bile flow, compared with the 18 control rats, entirely due to an enhancement of the bile salt independent fraction. The flow of bile salts (expressed in nmol/min/100 g) did not differ significantly in treated and control rats. Ten control and 10 treated rats were killed after the bile flow studies and their livers were weighed and homogenized for study of the enzymes in the microsomal fraction. Livers of diuretic-treated rats were significantly ($p<0.02$) heavier than those of control rats. Ethylmorphine demethylase, aminopyrine demethylase, and aniline hydroxylase activities were 18, 25, and 37% greater in treated rats than in the control rats ($p<0.05$, $p<0.05$, and $p<0.02$, resp.). UDP-glucuronyltransferase activity toward phenolphthalein, *p*-nitrophenol, and bilirubin was increased 38, 45, and 170% by the diuretic treatment ($p<0.02$, $p<0.02$, and $p<0.002$, resp.). Cytochome P-450 activity was not significantly altered in spironolactone-treated rats compared to controls. It is concluded that the effects of spironolactone on bile flow and hepatic microsomes could account for attenuation of the pharmacological effect of various drugs.

8715 EFFECT OF Na$^+$ ON BILE ACID UPTAKE BY ISOLATED RAT HEPATOCYTES: EVIDENCE FOR A HETEROGENEOUS SYSTEM. (Eng.) Anwer, M. S.; Hegner, D. (Fachbereich Tiermedizin der Universitat Munchen, Munchen, W. Germany). *Hoppe Seylers Z. Physiol. Chem.* 359(2):181-192; 1978.

The effect of Na$^+$ on cholate (C) and taurocholate (TC) uptake by isolated rat hepatocytes was investigated, to further characterize the Na$^+$ dependency of hepatic bile acid uptake and to test the hypothesis that hepatic bile acid uptake occurs through a multicarrier transport system. Uptake rates of both C and TC were decreased significantly when Na$^+$ was replaced by K$^+$, Li$^+$, or choline, suggesting that part of the bile acid uptake is Na$^+$-dependent. The Na$^+$-independent uptake rate of C (50-60%) was about three times higher than that of TC. Since the specific cation used to replace Na$^+$ did not affect the Na$^+$-independent uptake rate significantly as the cation was varied, Na$^+$ was replaced by choline in all other experiments. Above 200 μM C or TC, the initial bile acid uptake rates increased linearly both in the presence and absence of Na$^+$. The slope of this "nonsaturable" component showed no Na$^+$ dependency, making it possible to calculate the Na$^+$-dependent uptake rate by subtracting the Na$^+$-independent uptake rate from the uptake rate in the presence of Na$^+$. Hyperbolic curves were obtained for Na$^+$-dependent uptake of both bile acids. Subtraction of the nonsaturable component from the Na$^+$-independent uptake rate also resulted in hyperbolic curves for both C and TC. These results indicate that both bile acids are transported into hepatocytes by (a) a nonsaturable uptake process, (b) a Na$^+$-independent saturable uptake process, and (c) a Na$^+$-dependent saturable uptake process. The inhibition of bile acid uptake by KCN (2 mM) and Oligomycin (20 μg/ml) was as follows: saturable Na$^+$-independent C uptake was inhibited by 60 ± 4% and 57 ± 5%, resp., saturable Na$^+$-dependent C uptake by 55 ± 4% and 30 ± 2%, resp., Na$^+$-independent TC uptake by 65 ± 6% and 44 ± 3%, resp., and Na$^+$-dependent TC uptake by 57 ± 4% and 29 ± 3%, resp. Uptake by the two saturable components was also inhibited 33-100% by other bile acids or analogues. These results suggest the operation of carrier-mediated, energy-requiring processes. The relationship between Na$^+$ concentration and the Na$^+$-dependent uptake rate was sigmoidal. The maximal uptake rate, rather than the K$_m$, was affected by Na$^+$, suggesting that more than one Na$^+$ act as cosubstrates in the transport of one bile acid molecule and that Na$^+$ exerts a stimulatory effect on the translocation of the bile acid-carrier complex across the membranes. Na$^+$-dependent uptake was inhibited by ouabain (0.1 or 1.0 mM), suggesting that this uptake process is linked to the activity of membrane-bound (Na$^+$-K$^+$) ATPase. Inhibition and competition studies suggested that C and TC share a common Na$^+$-independent transport system, while there are at least two Na$^+$-dependent transport systems for TC, one of which is shared by C.

8716 BILE ACID CONJUGATION IN ORGAN CULTURE OF HUMAN FETAL LIVER. (Eng.) Haber, L. R.; Vaupshas, V.; Vitullo, B. B.; Seemayer, T. A.; de Belle, R. C. (Montreal Children's Hosp., 2300 Tupper St. C-1220, Montreal, Quebec H3H 1P3, Canada). *Gastroenterology* 74(6):1214-1223; 1978.

An organ culture system for prolonged maintenance of human fetal liver was developed and used to investigate the formation of bile acid conjugates. Multiple liver specimens were obtained from human abortuses and stillbirths ranging from 10 to 29 weeks of gestation. Within 3 hr of hysterotomy, small fragments of liver were established in organ culture. The morphological integrity of the explants was demonstrated by light and electron microscopy. Functional viability was determined by adding radiolabeled primary bile acid to the medium and assaying the taurine and glycine conjugates formed. Primary bile acid was taken up by the tissues, conjugated with taurine and glycine, and secreted into the medium at a constant rate during 10 days *in vitro* and in constant increments during a selected 24-hr period. Human fetal liver survived intact for periods up to 10 days *in vitro*. Taurine conjugates of the primary bile acids were seen to predominate throughout gestation, and the mean glycine to taurine ratio was 0.32. Conjugates of cholic acid were synthesized in preference to those of chenodeoxycholic acid ($p<0.05$). The glycine to taurine ratio was significantly greater ($p<0.001$) when chenodeoxycholate was used as substrate compared with cholate in liver of the same gestational age. There was a tendency for the glycine to taurine ratio to increase with advancing gestational age ($p<0.01$). Supplementation of the medium with 3.75 x 10^{-4} M taurine resulted in enhanced taurocholate formation ($p<0.001$) with a concomitant decrease in glycocholate synthesis ($p<0.001$), suggesting competitive inhibition. This finding suggests that there is one acyl transferase system for both taurine and glycine. In medium supplemented with 2 x 10^{-6} M hydrocortisone, there was a reversal of the glycine-taurine ratio, which increased from a mean of 0.49 in the control group to a mean of 1.74 ($p<0.001$) in the experimental group.

8717 BILE ACID ESTER SULFATION IN THE HAMSTER AND MAN. (Eng.) Galeazzi, R.; Kok, E.; Javitt, N. B. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* (Baltimore: University Park Press): 71-73; 1977.

To determine the sites of bile acid synthesis, the proportion of ester sulfates in the plasma of hamsters that underwent bile duct ligation was compared with that in hamsters that underwent either bilateral renal pedicle or bilateral ureteral ligation. In addition, serum bile acids were analyzed in hepatitis B surface antigen (HBsAg)-positive patients. The proportions of serum cholate and chenodeoxycholate in the hamsters that underwent bile duct ligation were similar to those in the animals that underwent either renal pedicle or ureter ligation, indicating that considerable ester sulfation occurs in animals having no circulation to the kidneys. Total serum bile acids in the patients with HBsAg ranged from 18 to 37 μg/ml, and the proportions of chenodeoxycholate and cholate were approximately the same. In two patients with advanced renal disease, the proportion of sulfates in the serum was greater than that found in similar individuals with normal renal function. The results in hamsters indicate that there is considerable extrarenal sulfation of bile acids, probably in the liver. In man, the association of increased ester sulfates of bile acids in plasma in advanced renal disease may also imply an extrarenal source for their synthesis.

8718 CONJUGATION AND SULFATION OF LITHOCHOLIC ACID IN FETAL LIVER. (Eng.) Watkins, J. B.; Brown, E. R. *In: Bile Acid Metabolism in*

Health and Disease, Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976. (Baltimore: University Park Press): 65-70; 1977.

To determine whether the fetal liver is capable of sulfating lithocholic acid, thus rendering it less toxic and less readily reabsorbed by the intestine, in a manner similar to that found in the adult liver, bile acids were extracted from meconium from 15 newborn infants. In addition, experiments were carried out in a sheep model. Sulfated and nonsulfated bile acid conjugates were identified by gas-liquid chromatography and gas-liquid chromatography-mass spectroscopy. Of the bile acids isolated, 40-60% were found in the sulfate fractions. The majority of the secondary bile acids isolated were as sulfated derivatives, with nearly 60% of the sulfates being lithocholic acid principally as glycolithocholic acid sulfate, with the remainder being either glycodeoxycholic or glycoursodeoxycholic acid. Cholic and chenodeoxycholic acids were isolated predominantly in the nonsulfate fraction and principally as their taurine conjugates. Similar results were obtained in a fetal sheep model. Tracer doses of 24-^{14}C-24-lithocholate were administered i.v. to five chronic fetal sheep preparations, which were sacrificed 6-53 hr later. Maternal tissues contained 23 ± 4.6% of the recovered dose of ^{14}C-lithocholic acid injected into the fetus. The distribution of the label recovered in the mother was 78.5 ± 9.4% as taurolithocholate, 9.0 ± 3.6% as glycolithocholate, and 10.1 ± 5.2% as taurolithocholic acid sulfate. In the fetus, 91.4% of the lithocholate was conjugated with taurine and secreted into bile or intestine with a mean of 9.0% having been sulfated, the percentage of sulfation increasing with time. These experiments demonstrate that considerable quantities of sulfated lithocholic acid and other maternally derived secondary bile acids are found in the intestinal contents of the human infant at birth. The fetus may excrete and possibly detoxify maternally derived lithocholic acid either by excretion across the placenta or by the hepatic uptake, conjugation, sulfation, and then secretion into the fetal intestine. The high concentration of sulfated conjugates in meconium indicate that sulfation may represent a truly excretory process for the fetus and that these bile acids are not reabsorbed from the fetal intestine. Glycine-conjugated lithocholate may be sulfated more readily than the taurine-conjugated or the free bile acid.

8719 METABOLISM OF BILE ACIDS. V. METABOLISM OF URSODEOXYCHOLIC ACID IN RHESUS MONKEY. (Eng.) Ota, M.; Matsumoto, N.; Kuramoto, T.; Hoshita, T. (Hiroshima Univ. Sch. Medicine, Hiroshima, Japan). *Hiroshima J. Med. Sci.* 26(4):253-262; 1977.

The metabolism of p.o.-administered, radiolabeled ursodeoxycholic acid was studied in rhesus monkeys. After 24-[^{14}C]ursodeoxycholic acid administration (30 mg/kg), the maximum plasma level was observed at 30 min in two animals and at 8 hr in one monkey; the levels decreased biphasically in all animals thereafter. Most radioactivity was excreted in the feces, with transient elimination in the urine on the first day after administration. The biological half-life of ursodeoxycholic acid was approximately 2 days. Ursodeoxycholic acid in the liver was metabolized to tauroursodeoxycholate and glycoursodeoxycholate, which were excreted with the bile into the intestine. The taurine/glycine conjugate ratio in the bile varied with time after administration. The glycine conjugate predominated in the first 24 hr, and its proportion decreased thereafter; the proportion of the taurine conjugate excreted in bile increased in a complementary fashion. The conjugated bile acids were further hydrolyzed to free ursodeoxycholic acid, most of which was converted into lithocholic acid by intestinal microorganisms. Lithocholic acid was the major radioactive bile acid in the feces, but made up only a minor portion of biliary bile acids. Because of this, it seems likely that the lithocholic acid formed in the colon was poorly absorbed.

8720 SOME OBSERVATIONS ON THE MORPHOLOGICAL EVIDENCE FOR MECHANISM OF THE BILE SECRETION. (Eng.) Shin, Y. C. (Coll. Medicine, Korea Univ. 4, 2nd St., Myungyun-Dong, Chongno-Ku, Seoul, South Korea). *Acta Anat.* 100(4):499-511; 1978.

Bile secretion was studied ultrastructurally in the goldfish liver. The hepatocytes were seen to be closely packed between the sinusoids. Duct cells were embedded between the hepatocytes. The hepatocytes contained bile canaliculi. The lumina of these bile canaliculi were nearly obstructed with numerous microvilli. The mitochondria were similar in shape and distribution to those of mammalian hepatocytes. Lysosomes were usually present, and many of them consisted of homogenous material. These dense bodies showed acid phosphatase activity. The rough endoplasmic reticulum (RER) appeared as parallel arrays of flattened cisternae. The RER contained fibrillar material with occasional granules of low or moderate electron density. The smooth endoplasmic reticulum (SER) was especially prevalent in the vicinity of the Golgi apparatus. These smooth-surfaced tubules sometimes appeared to be in continuity with the RER. Smooth tubules in the vicinity of the Golgi apparatus were associated with linearly sacculated tubules. Isolated vacuoles containing cloudy material similar to that within the sacculated tubules and within the bile canaliculi were observed between the Golgi apparatus and the intracellular bile canaliculus and seemed to be derived from the linearly sacculated tubules associated with the Golgi apparatus. Some vacuoles were fused with the luminal cytolemmas of the bile canaliculus. It is concluded that these vacuoles participate in the transport of bile constituents. The duct cells showed no ultrastructural evidence to suggest that they are involved in bile secretion.

8721 EFFECT OF BILE SALTS ON THE BILIARY EXCRETION OF GLYCODIHYDROFUSIDATE IN THE

RAT. (Eng.) Montet, J. C.; Gerolami, A. (Unite de Recherches de Pathologie Digestive, INSERM, 46, Bd. de la Gaye, 13009 Marseille, France). *Can. J. Physiol. Pharmacol.* 56(2):163-167; 1978.

The biliary elimination of glycodihydrofusidate (GDHF), a structural analogue of bile salts, was studied in bile fistula rats to determine if GDHF and bile salts compete for biliary excretion or if bile salts increased GDHF transport as they do for BSP. GDHF was excreted in bile with a maximal excretory rate (T_m=0.80 μmol/min/kg) much lower than that of bile salts. When an i.v. bolus injection of 3 μmol of GDHF was followed after 2 min by a continuous dehydrocholate perfusion (10 μmol/min/kg), biliary excretion of GDHF was increased 24% in comparison with that in control rats. When the biliary T_m had been attained by continuous perfusion of GDHF at a rate of 1.35 μmol/min/kg, taurocholate or dehydrocholate infusion increased this T_m to a similar degree. The effects of dehydrocholate and taurocholate on GDHF biliary secretion suggest a stimulatory effect of bile salts on canalicular excretion of the drug. The results are similar to those previously obtained concerning the effects of bile salt infusions on the T_m of BSP and suggest that hepatic transport of GDHF and bile salts occurs by routes that are distinct for canalicular transport in spite of the striking structural similarities between GDHF and bile salts.

8722 BRAN AND BILE: TIME-COURSE OF CHANGES IN NORMAL YOUNG MEN GIVEN A STANDARD DOSE.

(Eng.) Wicks, A. C. B.; Yeates, J.; Heaton, K. W. (Bristol Royal Infirmary, Bristol, England). *Scand. J. Gastroenterol.* 13(3):289-292; 1978.

The biliary response to a standard dose of bran was evaluated in 12 healthy men, and the time-course of previously observed changes in bile acid levels and biliary cholesterol saturation produced by dietary bran was investigated. All subjects added 15 g of bran to their usual diet and underwent aspiration of bile rich duodenal contents at 0, 1, 2, 4, and 6 weeks. In the 6-week sample, but not earlier, there was a significant decrease in the amount of deoxycholate (from 22.7 ± 2.8% to 16.5 ± 1.8%, $p<0.02$) and an increase in that of chenodeoxycholate (from 30.1 ± 1.6% to 34.9 ± 2.2%, $p<0.02$). Bile was unsaturated with cholesterol at the beginning of the experiment and remained so throughout. The delay in the action of bran on deoxycholate may occur because it reduces the formation of deoxycholate in the colon and does not merely impede its absorption.

8723 BILIRUBIN METABOLISM: STATE OF THE ART.

(Eng.) Schmid, R. (Univ. California, San Francisco, HSW 1120, San Francisco, CA 94143). *Gastroenterology* 74(6):1307-1312; 1978.

Recent chemical and biochemical observations concerning bilirubin metabolism are reviewed. Aspects of bilirubin structure, with particular emphasis on the various pigment isomers and the importance of intramolecular hydrogen bonding are considered, and the hepatic conjugating mechanism and bilirubin conjugates are discussed. The conjugating mechanism of the liver cell seems to serve the sole purpose of altering the involuted hydrogen-bonded conformation of bilirubin IX by esterifying its two propionic acid groups with carbohydrate moieties. Only the bilirubin isomers that can form intramolecular hydrogen bonds, as in the natural bilirubin IX_{α}, require conjugation for excretion. Other isomers, including the artificial isomers IX_{β}, γ, and δ, and probably the photochemically-produced E isomers of bilirubin IX_{α}, can be excreted directly in bile.

8724 EFFECTS OF SATURATED AND UNSATURATED FATS GIVEN WITH AND WITHOUT DIETARY CHOLESTEROL ON HEPATIC CHOLESTEROL SYNTHESIS AND HEPATIC LIPID METABOLISM.

(Eng.) Bochenek, W.; Rodgers, J. B. (Albany Medical Coll., Albany, NY 12208). *Biochim. Biophys. Acta* 528(1):1-16; 1978.

The effects of both dietary cholesterol and of fatty acid composition of the diet on hepatic cholesterol synthesis were studied in rats. Cholesterol synthesis was evaluated by measuring 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMCoA) activity and by determining the rate of ^{3}H-labeled sterol production from ^{3}H-mevalonate. The results were correlated with sterol balance data and hepatic lipid content. The mean total hepatic lipid levels in rats fed a diet containing either saturated or unsaturated fat and no cholesterol were similar to those in controls fed a normal rat-chow diet. The total hepatic lipid levels in rats fed a high-cholesterol diet (1% of diet) were significantly higher ($p<0.001$) than the control level, and the highest levels (700 ± 153 mg total lipids) were found in the rats fed the high-cholesterol and unsaturated fat diet as opposed to the levels (453 ± 74 mg) in those fed the high-cholesterol and saturated-fat diet. The mean total hepatic cholesterol level in rats fed the low-cholesterol and saturated-fat diet was significantly lower than that in controls (23 ± 4.0 versus 28 ± 4.2 mg, $p<0.05$); the levels in rats fed the high-cholesterol and saturated-fat diet (50 ± 19 mg, $p<0.005$) and in rats fed the high-cholesterol and unsaturated-fat diet (124 ± 42 mg, $p<0.001$) were significantly higher than the control level. Fecal sterol outputs were similar in rats consuming either saturated or unsaturated fats. HMCoA activity was significantly higher in rats fed the low-cholesterol diet than in those fed the high-cholesterol diet both when the dietary fat was saturated (673 ± 358 versus 175 ± 91 pmol/mg protein/min, $p<0.001$) and when the dietary fat was unsaturated (446 ± 329 and 62 ± 14 pmol/mg/min, $p<0.002$). The levels of HMCoA activity were significantly lower in all animals fed the saturated-fat diet compared with controls ($p<0.05$), in those fed the high-cholesterol and unsaturated-fat diet compared with those fed the high-cholesterol and saturated-fat diet ($p<0.002$), and in those fed the unsaturated-fat diet compared with the controls ($p<0.005$ for high-cholesterol diet and $p<0.1$ for ow-cholesterol diet). ^{3}H-labeled sterol prouction from ^{3}H-mevalonate was significantly higher n rats fed the low-cholesterol diet than those fed he high-cholesterol diet both when the dietary fat as saturated ($p<0.05$) and when it was unsaturated $p<0.001$). Sterol synthetic activity was signifiantly lower in animals fed the saturated fat diets $p<0.005$ for low cholesterol, $p<0.001$ for high holesterol) and in those fed the unsaturated fat iets ($p<0.001$) than in the controls. Cholesterol onsumption decreased the percentages of essential olyunsaturated fatty acids. It is concluded that ietary cholesterol alters cholesterol and fatty cid metabolism in the liver and that this effect s enhanced by dietary unsaturated fats.

725 EFFECTS OF CHOLESTEROL FEEDING ON SYNTHESIS AND METABOLISM OF CHOLESTEROL AND ILE ACIDS IN GERMFREE RATS. (Eng.) Gustafsson, B. .; Angelin, B.; Einarsson, K.; Gustafsson, J. A. Karolinska Institutet, Stockholm, Sweden). *J. ipid Res.* 18(6):717-721; 1977.

he influence of cholesterol feeding on cholesterol ynthesis and fecal excretion of bile acids was tudied in germfree rats. Four germfree rats were ed a basal diet containing 0.004% cholesterol, nd four germfree rats received the same diet suplemented with 0.4% cholesterol for 2 weeks. Choesterol synthesis was studied by assaying the -hydroxy-3-methylglutaryl coenzyme A (HMG CoA) eductase activity in the liver microsomal fraction. holesterol feeding decreased the mean HMG CoA eductase activity from 28.5 ± 6.6 to 9.1 ± 0.7 mol/mg protein/min. In another experiment, four ermfree rats received the basal diet and four ermfree rats, the cholesterol-enriched diet. After weeks, feces were collected in two 4-day pools or analysis of bile acids. The main fecal bile cids were cholic acid and β-muricholic acid, comrising more than 95% of total bile acids. Cholic cid was increased from 3.9 ± 0.2 to 9.9 ± 1.2 g/kg/day and β-muricholic acid from 6.6 ± 0.5 to 1.8 ± 3.1 mg/kg/day. The percentage of cholic cid decreased from 37.1 ± 1.1 to 31.2 ± 1.0%. ermfree rats, like conventional rats, have the bility to compensate for an increased input of ietary cholesterol by inhibition of cholesterol ynthesis and stimulation of bile acid synthesis. he synthesis of chenodeoxycholic acid (inferred rom the fecal excretion of β-muricholic acid) s stimulated to a greater extent than that of holic acid.

726 IMPAIRMENT OF HEPATIC CHOLESTEROL SYNTHESIS FROM SQUALENE AND THE FUNCTION F HEPATIC STEROL CARRIER PROTEIN SYSTEM BY AGEING. Eng.) Takeuchi, N.; Koga, M.; Yamamura, Y.; anaka, F.; Yamaguchi, Y.; Uchida, K. (Osaka Univ. osp., Fukushima-ku, Osaka, Japan 553). *Exp. Gerntol.* 13(1/2):1-7; 1978.

holesterol synthesis from squalene was measured n adult and in developing male Sprague-Dawley ats, and the effects of cytosol fractions from different age-groups on cholesterol synthesis of the hepatic microsomes from respective groups were compared *in vitro*. Incorporations of squalene and mevalonate into cholesterol in hepatic microsomes and cytosol obtained from growing (4-week-old) or young (2-month-old) rats were higher than those in microsomes and cytosol from adult rats. When the microsomes from growing or young rats were combined with the cytosol from adult rats instead of with young cytosol, the incorporation rates of squalene and mevalonate into cholesterol were decreased. When adult microsomes were combined with young cytosol, cholesterol synthesis from mevalonate was increased, but that from squalene was not. Cytosol fractions from cholesterol-fed rats did not inhibit cholesterol synthesis from squalene in the microsomes from nontreated rats, and the normal cytosol did not influence cholesterol synthesis in the microsomes from cholesterol-fed rats, suggesting that the elevation of serum cholesterol in aged animals did not affect the activity of the cytosol fraction. It is concluded that the function of the hepatic sterol carrier protein is probably impaired by ageing process.

8727 THE EFFECT OF AGEING ON THE BILIARY EXCRETION OF OUABAIN IN THE RAT. (Eng.) Kitani, K.; Kanai, S.; Miura, R.; Morita, Y.; Kasahara, M. (Tokyo Metropolitan Inst. Gerontology, Itabashi-ku, Tokyo, Japan). *Exp. Gerontol.* 13(1/2): 9-17; 1978.

Studies were carried out to gain information regarding age-related changes in hepatic elimination and biliary excretion of ouabain in the rat. The plasma concentration and biliary excretion of ouabain were determined in 3-, 6-, 16-, 18-, and 24-month-old male Wistar rats that each received an i.v. injection of ^{3}H-ouabain (0.4 mg/100 g). The plasma ouabain concentration increased with age, an effect most clearly seen in plasma samples taken at 2 and 5 min after injection. In 3-month-old rats, the level was 9.3 ± 1.1 μg/ml at 2 min and 5.1 ± 1.9 μg/ml at 5 min; in 24-month-old rats, it was 19.9 ± 2.4 μg/ml and 9.1 ± 1.0 μg/ml, resp. The difference was greater between 3- and 6-month-old rats than between 6- and 24-month-old rats. As time elapsed after ouabain injection, the age difference in plasma concentration decreased. The biliary excretion rate of ouabain was highest in the first 10-min bile sample in 3-month-old rats, and the excretion rate decreased thereafter. In contrast, excretion in 6-month-old or older rats was lower in the first sample, and the peak excretion was observed in the second 10-min sample. In the first 10-min sample, the excretion rate of 24-month-old rats was less than one-third of that in 3-month-old rats. Spironolactone pretreatment (7.5 mg/100 g/day) for 4 days in 16-month-old rats accelerated biliary ouabain excretion by an average of approximately 30%, in comparison with that in controls. The cumulative excretion rate in these rats approached the level seen in 6-month-old rats. The results indicate that there are age-related differences in ouabain elimination. These differences may be due to changes in bile flow rate.

8728 IN VITRO AMINO ACID TRANSPORT INTO BRAIN REGIONS OF RATS WITH A PORTACAVAL ANASTOMOSIS.

(Ita.) Rigotti, P.; Pizzolato, G.; Zanchin, G.; Bonino, M.; Vassanelli, P.; Battistin, L. (Istituto di Patologia Speciale Chirurgica, Padova, Italy). *Acta Chir. Ital.* 33(3):486-492; 1977.

A preliminary study of the uptake of amino acids by slices of forebrain, cerebellum, mesodiencephalon, and pons medulla of rats is presented. Male Sprague-Dawley rats were subjected to portacaval shunts; 1 month later, when the rats had a hunchbacked appearance and lowered reactions to stimuli, they were decapitated, and their brains were divided into four parts. Slices made from each of the four parts were placed into oxygenated medium and incubated 1 hr with four ^{14}C-labeled amino acids, then homogenized and analyzed for radioactivity. A decreased uptake of all four amino acids was revealed when compared with uptake by brain slices from unoperated controls. Glutamic acid uptake in comparison with controls was -4% in forebrain, -9% in cerebellum, -15% in mesodiencephalon, and -7% in pons medulla. The results for gamma-aminobutyric acid were -16% in forebrain ($p<0.10$), -2% in cerebellum, -10% in mesodiencephalon, and -9% in pons medulla. Glycine uptake was -22% in forebrain ($p<0.01$), -5% in cerebellum, -8% in mesodiencephalon, and -2% in pons medulla. Valine uptake was -16% in forebrain ($p<0.02$), -15% in cerebellum, -21% in mesodiencephalon ($p<0.02$), and -25% in pons medulla ($p<0.001$). These observations suggest that cerebral transport is affected in these experimental animals by portacaval anastomosis. The possible role of transport mechanisms impaired by portasystemic encephalopathy deserves further study.

8729 SOME OBSERVATIONS ON THE LIVER AND LUNG-MICROSOMAL-HYDROXYLATING ENZYME-ACTIVITY IN PORTO-CAVAL SHUNTED RATS.

(Eng.) Vassanelli, P.; Richter, C. (Istituto di Patologia Chirurgica dell'Universita di Padova, Policlinico, via Giustiniani, 35100 Padova, Italy). *Acta Chir. Ital.* 33(4):608-612; 1977.

Since the lungs and liver have the same embryological origin from primitive gut and since the presence of some microsomal drug metabolizing enzyme activities in the lungs has been established, liver and lung drug metabolism was examined in rats with portacaval shunt. P-nitroanisol demethylase activity was significantly increased in the shunted rats (0.54 nmol/min/mg protein) compared with that in controls (0.29 nmol/min/mg), whereas no significant differences in cytochrome P-450 content and NADPH-cytochrome c reductase activity were noted after shunt. Benzo(α)pyrene hydroxylase activity in microsomes isolated from the lungs of rats with portacaval shunt was also increased. It appears that portacaval shunt may alter drug metabolism in rats, and that drug administration in patients with a portacaval shunt should be approached with caution.

8730 THE RABBIT AS AN EXPERIMENTAL ANIMAL FOR THE STUDY OF PORTASYSTEMIC ENCEPHALOPATHY (PRELIMINARY DATA).

(Ita.) Vassanelli, P.; Battaglia, G.; Merigliano, S.; Zannini, P. (Istituto di Patologia Chirurgica dell'Universita di Padova, Padova, Italy). *Acta Chir. Ital.* 33(3):478-485; 1977.

The use of rabbits to study portasystemic encephalopathy is advocated and discussed. Fifty rabbits were given end-to-side portacaval shunts, performed below the gastroduodenal vein to maintain the blood flow to the liver. They were maintained on diets differing in protein content (19, 7.6, or 14.9% of the dry material). Body weight and electroencephalograms were studied. The average weight of the 10 rabbits subjected to the shunt was 2.1 kg at the time of the operations and 1.6 kg 10 days after the operations. On day 10 after the operations, 10 operated rabbits and 10 that had been sham-operated were decapitated, and their brains were analyzed for gamma-aminobutyric acid (GABA) levels. Rabbits given a standard diet (19% protein) died within 10 days, and those given either diet of hay survived as long as 2 months. In all the rabbits surviving the operation, central nervous system disturbances (incoordination and difficulty in walking) were observed. The animals showed evidence of exaggerated amounts of fear, a tendency to bang their heads against their cages, and altered electroencephalograms. In all the operated rabbits, the GABA levels were raised an average of 273 γ% mg of brain compared with an average of about 98 γ% mg of brain in the controls. It is concluded that the rabbit makes an interesting experimental model for portasystemic encephalopathy because the size of the animal yields large tissue and blood samples, neuropathy is manifest in a short period of time after the operation (7-10 days), and increased levels of cerebral GABA are detectable following the operation.

8731 SYNERGISTIC ACTION OF HEPATOCYTE MEMBRANE DEFECT AND ACTIVATED COMPLEMENT SYSTEM IN LIVER CELL DEATH: AN EXPERIMENTAL APPROACH TO FULMINANT HEPATIC FAILURE.

(Eng.) Liehr, H.; Grun, M.; Seelig, H. P.; Seelig, R.; Rasenack, U. (Medizinische Universitatsklinik, Josef-Schneider Str. 2, D-8700 Wurzburg, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 25(2):105-110; 1978.

The hypothesis that massive liver cell necrosis is caused by activation of the complement system as a result of a hepatocyte membrane defect was tested in Chbb Thom strain rats. The animals received 50, 100, 200, or 1,000 mg/kg galactosamine i.p. with or without the simultaneous i.v. injection of 1.5 mg/kg endotoxin. Doses of 50 mg/kg or 100 mg/kg galactosamine produced no liver cell necrosis, whether or not endotoxin was administered simultaneously. The 200 mg/kg dose led to moderate liver cell necrosis, and when administered together with endotoxin, the animals developed fulminant hepatic necrosis. Animals that received 1 g/kg galactosamine together with endotoxin died approximately 12 hr later, whereas animals receiving 1 g/kg galactosamine alone were alive at 24 hr after administration. In the animals that received endotoxin and the high dose of galactosamine, immunohistological examination revealed that the third complement component was already fixed on the hepatocyte plasma membranes at 3 hr after administration and was accumulated within areas of necrotic parenchymal cells at 12 hr. It appears that liver cell death is complement-mediated if the hepatocyte membranes are altered.

8732 SURGICALLY INDUCED HEPATIC FAILURE IN ANIMALS.

(Eng.) Ouchi, K.; Nose, Y.; Hermann, R. E. (Cleveland Clinic, Cleveland, OH). *Cleve. Clin. Q.* 44(4):171-180; 1977.

Three types of surgically-induced hepatic failure (anhepatic, ischemic, and jaundiced) were induced in mongrel dogs (4 dogs/group) to examine the usefulness of each of these animal models of hepatic failure for understanding the underlying mechanisms of this entity and developing human therapeutic modalities. The animals in the anhepatic group survived 26, 17, 17, and 11 hr after the total hepatectomy, and the postoperative course was similar in all four. The clinical observations (vomiting of gastric contents and coffee-groundlike material; spastic motions; clonic convulsions; shallow and rapid breathing succeeded by deep and slow breathing; decline in systolic blood pressure, pulse rate, and respiratory rate; and oliguria succeeded by anuria) and the biochemical observations (severe acidosis and hypercapnea; respiratory alkalosis but decrease in arterial pH; decrease in all blood cell components; decrease in serum Na^+ and Cl^- levels; increase in serum K^+ level; gradual decreases in total protein, albumin, and fibrinogen levels; increases in all liver function tests; decline of cholesterol and blood urea nitrogen levels; increase in creatinine, uric acid, ammonia, and free fatty acid levels; slight decrease in the levels of branched-chain amino acids; moderate increase in phenylalanine and tyrosine; and marked increase in glutamic acid, glycine, and histidine levels) were extremely similar to those in humans with hepatic insufficiency. The animals in the ischemic group underwent occlusion of the common hepatic artery either at the same time, 48 hr after (2 animals), or 6 days after portacaval anastomosis; one of the two animals in the second group did not develop coma, so that ligation of the proper hepatic artery was also carried out (6 days after portacaval anastomosis). The onset time of coma and the survival time after the last procedure were directly related to the time interval between portacaval anastomosis and hepatic artery ligation; onset of coma occurred at 7, 12, 14, and 35 hr, resp., and survival time was 16, 18, 18, and 38 hr, resp., for these animals. The biochemical changes were very similar to those in the anhepatic model except for higher levels of the nonbranched-chain amino acids. Following operations to induce obstructive jaundice, the remaining four animals survived 5, 5, 7, and 17 weeks after surgery, resp. As is frequently observed in patients with obstructive jaundice, the causes of death (and therefore the clinical and biochemical observations) varied; the dogs died of severe liver abscess with renal failure, pneumonia, gastric hemorrhage from multiple erosions, and hepatic failure from biliary cirrhosis, resp. It is concluded that these animal models closely resemble hepatic insufficiency in humans.

8733 BILIVERDIN INITIATES THE LIVER REGENERATION IN THE RAT--A HYPOTHESIS.

(Eng.) Okazaki, K.; Nishimura, H.; Arizono, H.; Nishimura, N.; Suzuki, Y. (Aichi Medical Univ. Sch. Medicine, Nagakute, Aichi, Japan). *Biochem. Biophys. Res. Commun.* 81(2):512-520; 1978.

The hypothesis that biliverdin initiates liver regeneration was investigated in intact, sham-operated, and 90% hepatectomized female Wistar rats. Biliverdin was absent in the plasma of intact and sham-operated animals, while the levels in hepatectomized animals killed at 5, 10, 20, 30, 45, 60, 120, and 180 min after ligating the blood vessels and bile ducts serving the right lateral and caudate lobes were 3.2, 2, 1.3, 1.3, 2, 1.7, 0.7, and 0.7 µg/ml, resp. In another series of experiments, the values were 4.2, 0.7, 0.7, 1.3, 1, 1.7, 0.7, and 0.3 µg/ml, resp. The mitotic indices determined in 100,000 hepatic parenchymal cells from intact rats at 24, 80, and 32 hr after a single i.p. injection of biliverdin (10 mg/100 g) were 446 ± 118, 862 ± 68, and 224 ± 8, resp. Mitotic indices determined 30 hr after the i.p. injection of 0.1 mg/100 g biliverdin, bilirubin, or hemoglobin were 130 ± 47, 129 ± 2, and 26 ± 2, resp. After a 1 mg/100 g injection, the levels were 92 ± 5, 106 ± 1, and 87 ± 5, resp., while the levels after a 10 mg/100 g injection were 862 ± 68, 20 ± 8, and 681 ± 134, resp. The results support the hypothesis that biliverdin initiates liver regeneration in rats.

8758 A MODIFIED PROCEDURE FOR THE RAPID PREPARATION OF EFFICIENTLY TRANSPORTING VESICLES FROM SMALL INTESTINAL BRUSH BORDER MEMBRANES: THEIR USE IN INVESTIGATING SOME PROPERTIES OF D-GLUCOSE AND CHOLINE TRANSPORT SYSTEMS. (Eng.) Kessler, M.; Acuto, O.; Storelli, C.; Murer, H.; Muller, M.; Semenza, G. (Laboratorium fur Biochemie, Eidgenossische Technische Hochschule, Universitatsstr. 16 and 2, CH-8092 Zurich, Switzerland). *Biochim. Biophys. Acta* 506(1):136-154; 1978.

A simplification of a previously described procedure for the preparation of brush border membranes from small intestine is described. The procedure was tested for Na^+-dependent D-glucose transport, and it was also used to study choline transport across the brush border membrane. The procedure is simple, rapid, does not necessarily require scraping, and can be started from fresh or frozen material. It can be scaled up easily, allowing a quick production of large amounts of brush border membrane vesicles. $CaCl_2$ (10 mM) is added to mucosal homogenates and allowed to stand in the cold for 15 min. The suspension is centrifuged at 3,000 x *g* for 15 min, and the supernatant is then centrifuged at 27,000 x *g* for 30 min. The pellet is resuspended in the 40 ml of buffer needed for the experiment, homogenized, and centrifuged at 27,000 x *g* for 30 min. The transport ability of the "calcium vesicles" obtained by these methods was compared with that of "EDTA vesicles" reported previously. The calcium vesicles constantly produced a longer lasting and higher overshoot peak of D-glucose (3-8 times as high as the equilibrium value with 1 mM D-glucose and 100 mM NaSCN as the initial outer concentration). Even NaSCN or NaCl gradients as low as 10 to 0 mM produced detectable overshoots. The calcium vesicles allowed the unequivocal demonstration of the transient accumulation of L-alanine, which was impossible with EDTA vesicles. After 2-3 days at 4 C, calcium vesicles generally showed only a minor decrease in their transport ability, demonstrating their stability. These results indicate that the calcium vesicles are excellently suited for transport studies. Choline transport was found to occur by a saturable component with a K_m of 83 ± 4 μM (at 20 C) and by a nonsaturable component. It was independent of the presence of Na^+, since it was not affected when K^+ was substituted for Na^+, and appeared to be nonelectrogenic. The charge movement associated with choline transport into these vesicles must be compensated by the exit of another cation or the entry of an anion, through the same transport agency as choline.

8759 DOES HEPARIN OCCUR IN MUCOSAL MAST CELLS OF THE RAT SMALL INTESTINE? (Eng.) Tas, J.; Berndsen, R. G. (Histological Lab., Univ. Amsterdam, 1^e Const. Huygensstraat 20, Amsterdam, Netherlands). *J. Histochem. Cytochem.* 25(9):1058-1062; 1977.

The chemical nature of the glycosaminoglycan (GAG) moiety of rat mucosal mast cell granules was investigated using microspectrophotometric analyses combined with model experiments using polyacrylamide films containing different types of purified GAG or GAG and basic protein. For the microspectorphotometric recording of metachromatic curves from toluidine blue O (TBO)-stained mucosal mast cells, a staining pH of 1.0 was chosen to avoid interference by orthochromatic staining. The time course of the metachromatic peaks recorded from the TBO-stained mucosal mast cells after mounting in glycerol was plotted. An "equilibrium level," with a mean peak wavelength of 553 ± 4.5 nm and 553 ± 4.1 nm for duodenal and jejunal mast cells, resp., was reached after about 6 hr. However, within 36 hr all mast cells in the sections had faded completely. When the same technique was applied to peritoneal and mesenteric mast cells, a final mean peak wavelength of 514 ± 3.5 nm and 516 ± 5.2 nm, resp., was obtained. The equilibrium level was reached after about 5 days in both cases, and metachromatically stained mast cells were present for about 8 days. Model experiments using polyacrylamide films that contained various types of GAGs showed that the metachromatic peaks recorded after staining at pH 1.0 instead of the more usual pH level of 5.0 differed only slightly. To imitate the chemical composition of rat mast cell granules more closely, model films containing GAG and chymotrypsinogen A were stained under the same conditions. After staining at pH 5.0, the metachromatic peaks shifted again to higher wavelengths on addition of this basic protein to the GAG in the model films. This shift was further increased by staining these films at pH 1.0. In all cases, the peak changes were most pronounced in glycerol. The peak of the metachromatic complex of TBO with heparin, the highest sulfated GAG used, was found to be less sensitive to the effects just mentioned. The results indicate that significant amounts of heparin do not occur in these cells and that lower sulfated GAG(s) are present in the granules.

8760 ROLE OF THE SMALL INTESTINE IN LIPID METABOLISM. SMALL INTESTINAL METABOLISM OF PLASMA FATTY ACIDS. (Ger.) Gangl, A. (II. Univ.-Klinik fur Gastroenterologie und Hepatologie, Garnisongasse 13, A-1090 Vienna, Austria). *Fortschr. Med.* 96(13):713-717; 1978.

The metabolism of plasma free fatty acids in the small intestine was studied by the i.v. injection of ^{14}C-labeled palmitic acid in rats and in 12 human volunteers undergoing suction biopsy of the small intestine. Two minutes after the injection of palmitic acid into rats, 1% of the radioactivity was found in the small intestinal mucosa, 42% in water soluble oxidation products (CO_2, keto acids, and other metabolites), and only 16% in triglycerides. Experiments with simultaneous i.v. injection of ^{14}C-palmitic acid and intraduodenal injection of ^{3}H-palmitic acid showed that the fatty acid introduced into the intestine was mainly esterified to triglyceride, while that injected i.v. was mainly oxidized and incorporated into phospholipids. An intraduodenal infusion of glucose (2 g/kg/hr), cholestyramine (5% suspension), taurocholate (10 and 30 mmol), or cholecystokinin (1.5 Ivy U/kg, s.c.) had no noteworthy effects on the intestinal metabolism of plasma free fatty acids, while intraduodenally administered alcohol (0.33 g/kg/hr) inhibited the intestinal oxidation of fatty acid by 60% and doubled both the palmitic acid incorporation into triglycerides by the intestinal mucosa and the serum triglyceride concentration. Intraduodenally administered oleic acid and monooleate (82 mg in a molar ratio of 2:1, emulsified in 10 mM taurocholate) doubled the intestinal uptake of plasma free fatty acids, quadrupled their incorporation into intestinal triglycerides, and caused a sixfold increase in the secretion of plasma free fatty acids into intestinal lymph triglycerides. Similar findings were also obtained in the volunteers. The findings indicate the great significance of the small intestine in lipid and lipoprotein metabolism.

8761 SPECIFIC LOCALISATION OF NEUROTENSIN TO THE N CELL IN HUMAN INTESTINE BY RADIOIMMUNOASSAY AND IMMUNOCYTOCHEMISTRY. (Eng.) Polak, J. M.; Sullivan, S. N.; Bloom, S. R.; Buchan, A. M. J.; Facer, P.; Brown, M. R.; *et al.* (Royal Postgraduate Medical Sch., London W12, England). *Nature* 270(5633):183-184; 1977.

To investigate the distribution of neurotensin in the human gastrointestinal tract, samples of normal stomach, intestines, gallbladder, and pancreas were obtained at surgery and examined using radioimmunoassay and immunocytochemistry. Large amounts of neurotensin-like reactivity were found in the ileal mucosa. The number of cells staining solely with antibodies to neurotensin diminished as the jejunum was reached, and they were extremely sparse in the duodenum. Neurotensin immunoreactivity was not detected in the stomach, pancreas, or colon by immunocytochemistry, but small amounts were detected by radioimmunoassay in the stomach (0.27 ± 0.03 pmol/g wet weight) and colon (0.50 ± 0.19 pmol/g). The amounts of immunoreactivity in the duodenal, jejunal, and ileal mucosae were found to be 0.24 ± 0.10, 2.82, and 16.2 pmol/g, resp., by this technique. No reactivity was found in the pancreas or gallbladder. The immunoreactive cells were located in the upper two-thirds of the villi and were often seen to communicate with the intestinal lumen by means of microvilli. When serial 1-μm sections were stained with antibodies reacting with enteroglucagon (EG) and vasoactive intestinal peptide (VIP), the positive cells were completely distinct from those stained by the neurotensin antibodies. The VIP- and EG-positive cells contained considerably smaller granules than did the neurotensin cells. These studies indicate that neurotensin cells occur in high concentrations in the ileal mucosa, with lesser quantities in the jejunum, duodenum, stomach, and colon. The morphological features of these cells suggest that they are sensitive to changes in the gut lumen, which may provide the stimulus for the release of the peptide directly into the circulation.

8762 BREAKDOWN OF MUCIN AND PLANT POLYSACCHARIDES IN THE HUMAN COLON. (Eng.) Vercellotti, J. R.; Salyers, A. A.; Bullard, W. S.; Wilkins, T. D. (Anaerobe Lab., Virginia Polytechni Inst. and State Univ., Blacksburg, VA 24061). *Can. J. Biochem.* 55(11):1190-1196; 1977.

To obtain an estimate of the extent to which complex carbohydrates are degraded by bacteria in the human colon, aqueous extracts of colon contents from four human subjects were separated into high and low molecular weight fractions by chroma-

aphy on a Sephadex G-100 column. The composi-
of these fractions was compared with the com-
tion of similar fractions from ileal contents,
, from material entering the colon. There
two distinct peaks; a high molecular weight
(approximately 100,000 daltons) and a low
cular weight peak (approximately 1,000 daltons)
ll subjects. In all subjects, the concentra-
of high molecular weight carbohydrate in the
m was more than twice the concentration of high
cular weight carbohydrate in the colon, in-
ting that breakdown of complex carbohydrate
rs in the colon. The high molecular weight
ohydrate fraction contained sugars character-
c of plant polysaccarides (arabinose, xylose,
ose, rhamnose) as well as sugars character-
c of mucin (fucose, hexosamines, sialic acids).
entrations of most of these sugars were uni-
ly lower in the colon than in the ileum. Since
molecular weight protein concentrations were
r in the colon than in the ileum of two of the
subjects tested, some degradation of protein
also occur in the colon.

TURNOVER OF RAT BRUSH BORDER PROTEINS AFTER MASSIVE INTESTINAL RESECTION.

(Eng.)
mann, M.; Starita-Geribaldi, M.; Isman, H.;
ka, P. (Laboratoire de Biochimie, Universite
ice, Chemin de Vallombrose 06200, Nice, France).
hem. Biophys. Res. Commun. 81(2):493-497; 1978.

etermine if the turnover of brush border mem-
e proteins is affected by massive intestinal
ction, the relative degradation rates of brush
er proteins were compared in male Wistar rats
had undergone 75% proximal small bowel re-
ion with those in rats that underwent sham
ation. After small bowel resection, there was
gnificant decrease in the ^{3}H:^{14}C ratios for
molecular weight (>70,000 daltons) brush bor-
proteins when compared with proteins of similar
isolated from sham-operated animals ($p<0.05$).
e results indicate that brush border membrane
ein turnover is affected by 75% small intes-
l resection. The authors conclude that this
ge may reflect immaturity of the villus epi-

IMMUNOCYTOCHEMICAL STUDY OF THE INTERACTION OF SOYBEAN TRYPSIN INHIBITOR WITH NTESTINAL MUCOSA.

(Eng.) Wilson, P. A.;
ed, R. N.; Hampe, M. M. V.; Holt, S. J. (Ian
es Ross Animal Res. Lab., P.O. Box 239,
ktown, New South Wales 2148, Australia). *Gut*
:260-266; 1978.

nvestigate further the cause of the pancreatic
rgement induced by orally ingested soybean
sin inhibitor (STI), antibodies raised against
nd purified by affinity chromatography were
to localize dietary STI in the rat gut by
escent immunocytochemical methods. This tech-
e permitted the clear intracellular demonstra-
of STI in the ileal mucosa of suckling rats; in adult rats no entry of STI into mucosal cells of the small intestine was demonstrated, being confined to the luminal surface of the mucosa. Although the passage of STI into and across the adult intestinal mucosa could not be excluded through the use of this technique, the results were consistent with a previously described intraluminal mode of action of STI, namely, that the pancreatic enlargement caused in sensitive species results from the inhibition of trypsin (which acts as the physiological inhibitor of the mucosal secretion of pancreotrophic hormones), thus resulting in the uninhibited secretion of these hormones.

8765 RELEASE OF VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) BY INTRADUODENAL STIMULI.

(Eng.) Schaffalitzky de Muckadell, O. B.; Fahrenkrug, J.; Holst, J. J.; Lauritsen, K. B. (Bispebjerg Hosp., Bispebjerg Bakke 23, DK-2400 Copenhagen NV, Denmark). *Scand. J. Gastroenterol.* 12(7):793-799; 1977.

To determine whether stimuli other than i.v. calcium or electrical stimulation of the vagal nerves will elicit the release of vasoactive intestinal polypeptide (VIP) into the circulation, the effects of intraduodenal infusion of amino acids, glucose, fat, HCl, ethanol, and saline on plasma VIP concentrations were investigated in seven normal human subjects and 12 anesthetized pigs. In addition, the plasma VIP concentration after the ingestion of a mixed meal was determined in six normal subjects, and the effect of HCl on plasma VIP concentration was determined in five postvagotomy patients. In normal subjects, the median peripheral blood plasma VIP concentration in the basal state was 4.3 pM (range 0-12.0 pM). No significant changes in the VIP concentration occurred after amino acid infusion (40 ml of a mixture of alpha and beta casein), glucose infusion (0.3 M, 40 ml), NaCl infusion (0.15 M or 1.5 M, 40 ml), or ingestion of a meal. In contrast, HCl (0.1 M, 40 ml), isotonic fat emulsion (20%, 40 ml), and ethanol (60 ml Vodka) infusion increased the plasma VIP concentration in all seven normal subjects; the mean peak values after HCl, fat, or ethanol were 9.8 (range 5.9-12.6), 7.5 (2.4-10.2), and 12.6 (7.8-16.8) pM, resp. Truncal vagotomy did not change the response produced by HCl, and the VIP level increased from 5.8 pM (range 0-11.6 pM) to 10.2 pM (7.5-13.0 pM) after HCl infusion in the vagotomized patients. The results from VIP determinations in the portal plasma of pigs following amino acid, glucose, fat, HCl, ethanol, or saline infusion confirmed the findings in the peripheral blood plasma of the normal human subjects and showed that the VIP levels in portal plasma were 1.6-2.9 times higher than the VIP levels in arterial plasma. The pH threshold to VIP release was 1.1-2.1, and the effect of HCl was not abolished by ganglionic blockade with hexamethonium (10 mg/kg). These studies show that intraduodenal HCl, fat, and ethanol stimulate VIP release. The lack of VIP response to a meal (which contained fat) may be explained by the fact that changes in VIP concentration are greater in the portal plasma than in the peripheral circulation: VIP release might be detectable in the portal circulation only.

8766 EFFECT OF PENTAGASTRIN AND SECRETIN ON CELL RENEWAL AND THE THREE DIMENSIONAL STRUCTURE OF THE JEJUNAL MUCOSA OF THE FASTED RAT. (Fre.) Bosshard, A.; Pansu, D.; Lambert, R. (Hopital Edouard-Herriot, F 69374 Lyon Cedex 2, France). *Gastroenterol. Clin. Biol.* 2(2):165-176; 1978.

The effect of pentagastrin and secretin on the renewal of cells and the structure of the jejunal mucosa were studied in male Wistar rats fasted for 48 hr. In the second 24-hr period of fasting, the rats were injected i.p. with pentagastrin (175 μg/100 g) or secretin (24.5 clinical U/100 g) divided into seven doses given at 4-hr intervals. One group of hormone-treated animals was injected with tritiated thymidine (50 μCi/100 g) at the same time as the first injection of hormone and then killed either at the end of 48 or 72 hr. Animals from the second hormone-treated group were killed every 4 hr during the third 24-hr period, with tritiated thymidine injected 30 min before sacrifice. Control fasted rats had significantly ($p<0.05$) lower labeling and mitotic indices compared to nonfasted control rats; the wet weight of the intestines and the thickness of the intestinal wall were also decreased compared with nonfasted rats. In fasted rats injected with secretin, there was a decrease of the labeling index followed by a decrease of the mitotic index during the third 24-hr period compared with fasted control rats; also, the number of short villi in the intestinal mucosa increased. After the pentagastrin injections, labeling and mitotic indices increased until, at 72 hr, they were significantly ($p<0.05$) higher in treated rats than in fasted controls. Pentagastrin also induced thickening of the serosal villi and of the mucosal layer. The results confirm the trophic effect of gastrin on cell renewal and the three dimensional structure of the jejunum and the antitrophic effects of secretin on these parameters.

GENERAL

8774 RETROGRADE PANCREATIC PHLEBOGRAPHY WITH SIMULTANEOUS BALLOON OCCLUSION OF PORTAL AND ARTERIAL FLOW. AN EXPERIMENTAL STUDY. (Ger.) Gunther, R.; F bsguth, A.; Georgi, M.; Hohn, P. (Institut fur Klinische Strahlenkunde der Universitat, Langenbeckstrasse 1, 6500 Mainz, W. Germany). *Fortschr. Geb Roentgenstr. Nuklearmed.* 128(2):151-155; 1978.

The possibility of visualizing the venous system of the entire pancreas by retrograde portal contract injection (with Angiografin) and simultaneous balloon occlusion of the portal vein, celiac trunk, and superior mesenteric artery was studied in 12 male dogs. Good filling of the major pancreatic veins was achieved in 7/12 dogs. The portal and arterial pressures altered considerably der the experimental conditions. A rise in the vels of serum transaminases was observed only ce, when there was thrombosis of the portal vein d branches of the hepatic veins. Apart from is case, there was no rise in the levels of transinases or of α-amylase. After a total occluon of 40 min (6-min periods of occlusion alterting with 2-5 min of flow), there were only minor stological changes in the liver. Short-term terial balloon occlusion seems feasible in man well, but a transumbilical approach should be osen.

75 BEHAVIOR OF SOME SERUM ENZYMES FOLLOWING LIGATION OF THE SUPERIOR MESENTERIC ARRY IN THE RAT (PRELIMINARY REPORT). (Ger.) Rupecht, H.; Gaida, P.; Keil, E.; Kunath, H.; Klett, (Chirurgische Universitatsklinik und Poliklinik, iedrich-Schiller-Universitat, Bachstrasse 18, R-69 Jena, E. Germany). Z. *Exp. Chir.* 10(6):351-6; 1977.

evaluate serum enzyme tests as diagnostic tools r acute intestinal ischemia, the effect of ligaon of the superior mesenteric artery on some rum enzymes was studied in adult female Wistar ts 0.5-8 hr after ligation. The ligation of the perior mesenteric artery caused marked increases the activities of the serum enzymes (aspartate ino transferase, alanine amino transferase, lipase, pha-amylase, isocitrate dehydrogenase, glutamate hydrogenase) and in the blood sugar level. The partate amino transferase activity increased markly with time between the 2nd and 8th hr, while e alanine amino transferase activity reached its ximum between 3 and 4 hr, the lipase activity beeen 1 and 3 hr, the alpha-amylase activity between and 4 hr, and the glutamate dehydrogenase activity tween 3 and 4 hr. The isocitrate dehydrogenase tivity increased with time between the 2nd and h hr. The changes in the enzyme activities e probably due to the shock and to the reduced flow of portal vein blood to the liver (and us to additional hypoxic damage of this organ). e findings indicate that the serum enzyme tests y be valuable in the diagnosis of early stages of ute intestinal ischemia.

DIAGNOSTIC PROCEDURES

8783 ARTERIOPORTOGRAPHY. (Eng.) Herlinger, H. (St. James' Univ. Hosp., Leeds, England). *Clin. Radiol.* 29(3):255-275; 1978.

The results of 82 arterioportographic (AP) examinations of 78 patients are described. Because splenoportography (S) can give inadequate or misleading information and because there are contraindications and serious potential complications associated with its use, AP has superseded it in the study of portal hypertension. There are no contraindications to AP, complications are totally avoidable, and the information obtainable comprises both the arterial and venous phases, encompasses the entire portal system, allows a limited estimate of flow dynamics, and contributes to planning for shunt surgery. The technique of AP involves the catheterization of the celiac and superior mesenteric arteries, of the inferior vena cava, and of the hepatic veins. In the cases reported, arterial phase findings included retroperitoneal malignancy (4), hepatoma complicating cirrhosis (5), pancreatitis, hepatic artery occlusion (underperfusion, 2), and a nontraumatic communication between the left hepatic artery and the left portal vein (1). Splenic artery catheterization and injection of an adequate amount of contrast medium, with good flow through the spleen, provided pictorial information virtually equal to that obtained by S. Venous phase information included morphological inadequacy (portal vein [PV], 2; splenic vein [SV], 4; superior mesenteric vein [SMV], 6), abnormality of flow (hepatofugal PV, 3; slow tidal SV, 8), occlusion (PV, 5; SV, 13; SMV, 5), and presence of thrombus (PV, 6; SMV, 11). Aids to interpretation of venous phase data are given with the warning that S should not be used to confirm the diagnosis of SV occlusion as hemorrhage from the spleen could occur. Wedged hepatic venography was discussed although it was not used formally in the current study to grade the severity of cirrhosis or to test for portal flow reversal. Criteria for the use or avoidance of mesocaval and distal splenorenal shunt procedures and for the use of percutaneous transhepatic portal catheterization and/or AP in the management of patients with portal hypertension are presented. The study demonstrates that AP is an angiographic method with comprehensive diagnostic potential, which is management oriented and useful for determining the suitability of patients for specific shunt surgery.

8784 CONCLUSIONS OF LP-X DETERMINATION IN MORE THAN 2,500 PATIENTS. (Eng.) Eder, G.; Weiss, W.; Neumayr, A.; Schuller, J.; Baumgartner, G. (Immuno Diagnostika, Vienna, Austria). *Protides Biol. Fluids Proc. Colloq.* 25:341-347; 1977.

The results of two different studies on the determination of serum lipoprotein X (LP-X) levels for the detection of extra- or intrahepatic cholestasis are presented. In one study, 800 healthy subjects were screened for LP-X, none of whom were found to have this factor in the serum. In the other study, 1,805 patients in a gastroenterology department were tested, 1,570 of whom had histologically confirmed hepatobiliary disease. The first LP-X test was positive in 28.9% of these patients. However, different results were recorded at follow-up 1 week later in 23.3% of 257 patients and at follow-up 2 weeks later in 51.5% of 68 patients. The LP-X test was positive in 92.8% of 181 cases of cholestasis. The test was positive in 77.6% of 165 patients with alcoholic liver diseases, in 63.7% of 91 patients with hepatitis B surface antigen (HBsAg)-positive acute hepatitis, in 50.0% of 66 patients with HBsAg-negative acute hepatitis, in 42.4% of 33 patients with chronic active hepatitis, and in 2.9% of 34 patients with chronic persistent hepatitis. LP-X was present in the sera of 44.4% of 54 patients with primary liver cancer, 48.8% of 170 patients with liver metastases, 5.1% of 99 patients with a tumor but no liver metastases, and in 23.3% of 194 patients with hematologic malignancies. LP-X occurred in 73.9% of 23 patients with osteomyelosclerosis but in less than 31% of other patients with hematologic diseases. The LP-X test was positive in 28.4% of 95 cases of cholelithiasis, 88.9% of 27 cases of cholelithiasis, and 35.0% of 40 patients with inflammatory bowel disease. LP-X testing is useful in the diagnosis of intra- and extrahepatic cholestasis.

8785 CHOLANGIOGRAPHIC APPEARANCE OF THE INTRAHEPATIC BILE DUCTS. (Eng.) Wojtowicz, J.; Karwowski, A. (Katedra Radiologii AM, ul. Szkolna 8/12, 61-833 Poznan, Poland). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 127(5):417-421; 1977.

The value of percutaneous transhepatic cholangiography (PTC) in the diagnosis of intrahepatic bile duct diseases was assessed by examining the cholangiographic appearance of the intrahepatic bile ducts in 134 cases. The patients underwent the procedure for gallstone disease (23 cases), evaluation of complications of gallbladder surgery (21), chronic pancreatitis (6), liver cirrhosis and chronic hepatitis (4), gallbladder or bile duct neoplasms (31), pancreas or papilla neoplasms (36), or liver neoplasms (13). Satisfactory filling of the peripheral bile ducts was obtained after drainage of bile and with the injection of a somewhat increased quantity of contrast medium into the biliary system. Generalized dilatation of the intrahepatic bile ducts was observed in all cases of mechanical obstruction. PTC was effective in detecting malignant neoplasms: the incidence of true positives was 36/40 and the incidence of true negatives was 89/94. The predictive value of a positive result was 36/41. Advanced liver cirrhosis with extrahepatic bile obstruction was characterized by PTC by dilatation with pronounced crowding and tortuosity of the bile ducts. Multiple abscesses associated with cholangitis were an incidental finding of PTC; these appeared as extravasations of contrast medium into the liver parenchyma communicating freely with the biliary system. The PTC appearance of surgical lesions of the choledochal duct, necrosis of a metastatic tumor, and of cystic dilatations of the peripheral branches of the biliary system are illustrated. These results show that PTC can be useful in the diagnosis of intrahepatic disease.

786 PLASMA BILE ACIDS FRACTIONATION BY GAS-
LIQUID CHROMATOGRAPHY: APPLICATION TO
EPATOCELLULAR DEFICIENCY INVESTIGATION. (Fre.)
ereziat, G.; Pepin, D.; Wolf, C.; Polonovski, J.
Laboratoire de Chimie Biologique, CHU Saint-Antoine,
7, rue Chaligny, 75571, Paris Cedex 12, France).
athol. Biol. (Paris) 25(8):559-564; 1977.

he four major bile acids, cholic, chenodeoxy-
holic, deoxycholic, and lithocholic acids, were
easured in plasma from patients with atresia of
iliary tract (3), viral hepatitis (5), and cir-
hosis (12), including alcoholic and posthepatic
isease. The method used was that of Nair em-
loying gas-liquid chromatography. Normal levels
stablished in this series were compared with
hose reported by other authors. In the presence
f cholestasis, the ratio of chenodeoxycholic acid
o cholic acid was equal to or less than one; when
epatic deficiency developed, the ratio of cheno-
eoxycholic acid to chclic acid was higher than
ne. A very high ratio was considered indicative
f progressive hepatic deficiency. Three patients
ith high levels of lithocholic acid had hepatic
isease with a fatal outcome.

787 COMPUTED TOMOGRAPHY OF THE GALLBLADDER.
(Eng.) Havrilla, T. R.; Reich, N. E.;
aaga, J. R.; Seidelmann, F. E.; Cooperman, A. M.;
lfidi, R. J. (Cleveland Clinic Foundation, 9500
uclid Ave., Cleveland, OH 44106). *Am. J. Roent-
enol.* 130(6):1059-1067; 1978.

linical experience with computer tomography (CT)
n 79 patients with suspected gallbladder disease
s presented. CT accurately diagnosed stones within
he gallbladder, either radiopaque or radiolucent,
n 78% of 50 patients with cholelithiasis. There
ere three false-positive CT examinations. In one
ase, laminated calcifications in the renal paren-
hyma adjacent to the gallbladder were mistakenly
dentified as gallstones. One patient had chronic
holecystitis with a thickened gallbladder wall and
dhesions, and the third had an inflammatory mass in
ne right liver lobe (no calculi). The 11 false-
egative studies included 4 patients with a non-
isualized gallbladder; in 5 patients, calculi were
issed completely. The CT scan correctly identified
of 7 patients with a functioning gallbladder with-
ut stones and 14 of 15 patients with nonfunctioning
allbladders without stones. Four patients without
holelithiasis but with either an abscess or gall-
ladder bed inflammation secondary to cholecystitis
ere all identified by the CT examination. One
atient with a nonvisualizing oral cholecystogram
nd negative reading of a plain film of the abdomen
ad a large laminated calculus shown by CT, which
ppeared to be outside the confines of the gall-
ladder and situated in the portal area. At laparo-
omy, a gangrenous gallbladder was found with perfora-
ion of a large gallstone into the liver bed and
orta hepatis. In two cases, the presence of hy-
rops secondary to cystic duct obstruction or to
ommon bile duct stones were noted on the CT scan.
he observations in these patients suggest that
anifestations of gallbladder disease such as hy-
rops, opaque and nonopaque gallstones, chronic
cholecystitis with thickened inflammatory walls, and secondary liver abscesses can be detected by CT. It is a useful technique for individuals in whom the gallbladder has failed to opacify on oral cholecystography, and can be a useful alternative to conventional radiographic or ultrasound examinations, giving an overall diagnostic accuracy greater than 80%.

8788 COMPUTED TOMOGRAPHY OF THE PANCREAS. (Eng.) Moss, A. A.; Kressel, H. Y. (Univ. California, Sch. Medicine, San Francisco, CA). *Am. J. Dig. Dis.* 22(11):1018-1027; 1977.

Experience with computed tomography (CT) in the diagnosis of pancreatic diseases is discussed, and numerous illustrations are presented. CT scanning demonstrates the normal pancreas in most cases. It is unusual to image the entire pancreas on a single CT scan. Except in extremely emaciated patients, a layer of peripancreatic fat separates the pancreas from the aorta and enables the superior mesenteric artery to be identified just posterior to the body of the pancreas. In detecting pancreatic abnormality, attention should be paid to alterations in morphologic configuration that produce diffuse or focal areas of pancreatic enlargement, and to nonhomogeneous pancreatic tissue that produces variations in pancreatic tissue density (CT number, attenuation coefficient). The most important sign of pancreatic carcinoma is focal enlargement of the head, body, or tail of the pancreas. When the tumor extends posteriorly, the peripancreatic fat plane may be obliterated by tumor extension. Acute pancreatitis causes either focal or more often diffuse enlargement of the pancreas. In some instances, the peripancreatic fat plane may be destroyed, and differentiation of localized pancreatic enlargement due to pancreatitis from that secondary to carcinoma often cannot be done solely on the basis of CT scanning. The CT scan in chronic pancreatitis may be normal, demonstrate calcific deposits within the pancreas, show an enlarged pancreatic duct, or reveal the pancreas to be small and atrophic. Pancreatic pseudocysts are readily detected by CT scanning due to the marked difference in the attenuation coefficients of pseudocysts and normal pancreatic tissue. The scan in pancreatic abscess characteristically shows an area of pancreatic enlargement that contains multiple ill-defined areas of low attenuation number. Disease within the peripancreatic lymphatic tissue produces a mass on CT scan that may be impossible to distinguish from pancreatic carcinoma. In some instances, however, the fat plane between the aorta, the mass, and the pancreas may be preserved and allow a preoperative diagnosis of peripancreatic lymphoma. CT scanning of the pancreas is a safe, rapid, and effective method of imaging the normal or abnormal pancreas of most patients who have a normal amount of body fat.

8789 CT SCANNING AND ULTRASOUND IN THE EVALUATION OF PANCREATIC PSEUDOCYSTS: A PRELIMINARY COMPARISON. (Eng.) Kressel, H. Y.; Margulis, A. R.; Gooding, G. W.; Filly, R. A.; Moss, A. A.; Korobkin, M. (Univ. California Sch. Medicine, San Francisco, CA 94143). *Radiology* 126(1):153-157; 1978.

A retrospective study of 12 surgically proved cases of pancreatic pseudocysts was carried out to assess computed tomography and ultrasound in the diagnosis of these lesions. Computed tomography correctly demonstrated six of eight uncomplicated pseudocysts and all of four infected pseudocysts. Ultrasound identified seven of the eight uncomplicated pseudocysts and two of the four infected pseudocysts. In the two remaining patients with infected pseudocyts, extensive bowel gas precluded optimal evaluation, and the limited examination failed to reveal evidence of an abnormal pancreatic fluid collection. One case of uncomplicated pseudocyst was missed by both tomography and ultrasound, but dilatation of the intrahepatic and common bile duct was noted. In the other case missed by tomography, scans were suboptimal in a markedly cachectic patient. The results indicate that errors by one modality are due to limitations not shared by the other method. This suggests a basis for the complementary use of computed tomography scanning and ultrasound in the evaluation of suspected pancreatic pseudocysts.

8790 STUDY OF PURE HUMAN PANCREATIC JUICE COLLECTED AFTER SECRETIN AND CERULEIN STIMULATION. (Fre.) Escourrou, J.; Frexinos, J.; Ribet, A. (Clinique des Maladies de l'Appareil Digestif, C.H.U. de Rangueil, F 31054 Toulouse, France). *Gastroenterol. Clin. Biol.* 2(1):29-37; 1978.

Pancreatic function after stimulation by simultaneous continuous infusion of 0.5 U/kg body weight/hr of secretin and 75 ng/kg body weight/hr of cerulein was studied in seven normal men. The patients had fasted for 36 hr and had no premedication except 10-20 mg *N*-butylhyoscine bromide used to produce duodenal hypotony when the catheter for collecting the pancreatic juice was introduced into the main pancreatic duct. The subjects were in the left-side position during the entire examination (60 min) to avoid contamination with gastric secretion. Samples were collected every minute for the first 15 min after injection of secretin and cerulein; thereafter, they were collected every 5 min. There was usually a latent period of 5 min before the pancreatic juice samples actually could be collected, which was attributed to the time the sample took to pass through the collecting catheter. The total collected volume varied from 118-210.7 ml and appeared related to the weight of the subject. The pancreatic juice pH was between 8.2-9.2. Bicarbonates rose to a maximum, varying from 116-140 mEq/l, at about 7-14 min. The sum of the bicarbonates and chlorides remained constant throughout the test for each subject and varied from 145.5 ± 1.7 mEq/l to 153.8 ± 0.9 mEq/l. Proteins, lipase, chymotrypsin, and amylase levels were also measured. The proportions of the different enzymes varied from one subject to another. It is concluded that collection of pancreatic fluid from the main pancreatic duct avoids contamination by bile or gastric juice with minimal danger to the subject.

8791 ^{99m}Tc-LABELED COMPOUNDS IN HEPATOBILIARY INVESTIGATIONS, AS EXEMPLIFIED BY STUDIES WITH HepatoBIDA. (Ger.) Wolf, F.; Kronert, E.; Regler, G. (Institut und Poliklinik fur Nuklearmedizin, Universitat Erlangen-Nurnberg, Krankenhausstrasse 12, 8520 Erlangen, W. Germany). *Fortschr. Med.* 96(9):455-462; 1978.

The pharmacokinetics and diagnostic usefulness of ^{99m}Tc-labeled 2,6-diethylacetanilidoiminodiacetic acid (HepatoBIDA) were studied in normal subjects and 52 patients with hepatobiliary disorders (mech anical obstruction of bile ducts, gallbladder and bile duct inflammation, dyskinesia, hepatic parenchymal lesion, liver metastasis, hydatid cyst, and hepatocellular carcinoma). HepatoBIDA was taken u by the liver very rapidly following the i.v. injec tion of 2-5 mCi. The plasma clearance was 420 ml/ min after 10 min, and 250 ml/min after 30 min (bod surface 1.73 m^2). The experimental studies on the patients showed that it is mandatory to obtain vis ual documentation of the marker passage by sequential scintigrams and to get functional graphs, especially from the complete examination field, the peripheral and central liver regions, the bile transporting system, and the small intestine. At present, the main indications for this examination are in the diagnosis of bile flow obstructio of mechanical or inflammatory origin and in the evaluation of therapeutic measures.

GASTROINTESTINAL DISEASES

ESOPHAGUS

824 ENDOSCOPY IN LYE BURNS OF OESOPHAGUS AND STOMACH. (Eng.) Poelman, J. R.; ausman, R. H.; Hoitsma, H. F. W. (Academic Hosp., ree Univ., De Boelelaan 1117, Amsterdam, Neherlands). *Endoscopy* 9(3):172-177; 1977.

he cases of two patients with caustic esophageal nd gastric injuries following lye ingestion are resented. The patients were a 52-yr-old woman nd a 67-yr-old man. Both presented with oral and haryngeal pain, burning pain behind the sternum nd upper abdomen, and hematemesis. Endoscopic xamination was omitted in the first patient beause of the danger of perforation. About 12 hr fter admission, the patient went into hypovolemic hock, and signs of peritonitis developed. At aparotomy, total resection of the stomach, spleen, nd gallbladder was performed because of massive ecrosis. A perforation was not found, and it was ssumed that the caustic solution had leaked through he stomach causing chemical peritonitis. A panreatic fistula and subphrenic abscess developed uring the postoperative period. Endoscopy was arried out in the second patient 6 hr after adission. Severe erosive, hemorrhagic, fibrinous sophagitis; gastric thrombosis of the superficial essels with hyperemia, edema, erosions, necrotic pots, and hemorrhage; and pyloric atony, hyperemia, nd edema were found. The duodenal mucosa was ormal. The patient was treated conservatively, nd the healing process was followed by repeat ndoscopy. Stenosis did not occur. The authors onclude that the development of the pancreatic fisula and subphrenic abscess in the first patient ight have been averted had endoscopy been performed.

325 ESOPHAGEAL DYSPHAGIA TREATED BY CRICOPHARYNGEAL MYOTOMY. (Eng.) West, E. ., Jr.; Baker, H. W. (Good Samaritan Hosp., Portand, OR 97201). *Am. Surg.* 43(11):703-708; 1977.

he results of cricopharyngeal myotomy in the reatment of 14 patients with dysphagia were analzed, and the technique is reviewed. Surgery is arried out via an oblique incision over the anerior border of the left sternocleidomastoid uscle in its lower one-half. The pharyngeal contrictors are identified and the cricopharyngeus s differentiated by the transverse fibers without midline raphe, and the fibers are divided verically with sharp dissection down to the esophageal ucosa. The incised fibers include the inferior ibers of the inferior pharyngeal constrictors as ell as the superior fibers of the circular esophgeal constrictors to insure complete division of he sphincter. This may also be facilitated by he use of a Foley catheter passed, then inflated nd pulled up by the anesthesiologist. If the yotomy is complete, the esophageal mucosa should ulge through the myotomy site. A small Penrose rain is placed in the retroesophageal space rior to closure of the incision. The patients ranged in age from 46 to 86 yr. Nine were roentgenographically proven to have cricopharyngeal dysfunction. Seven patients with cricopharyngeal hypertrophy without other evident current disease had excellent results from myotomy, including one with remote bulbar poliomyelitis. One patient each with Parkinson's disease, hypopharyngeal carcinoma, amyotrophic lateral sclerosis, and cerebrovascular accident had poor results. There were two complications. One patient had a postoperative hemorrhage that required reexploration and drainage of a hematoma. The other, an elderly patient with a cerebrovascular accident, died of aspiration pneumonitis postoperatively. The accurate diagnosis and treatment of dysphagia depends upon adequate history, examination, and appropriate testing. X-ray evidence, particularly cine esophagram, is the diagnostic medium of choice in cricopharyngeal dysfunction and hypertrophy. Section of this muscle can bring immediate relief of dysphagia in patients with otherwise intact swallowing mechanisms.

8826 EPITHELIAL DYSPLASIA IN CANCEROUS AND NONCANCEROUS ESOPHAGI. (Eng.) Sato, E.; Tokunaga, M.; Sakae, K.; Mukada, T.; Sasano, N. (Kagoshima Univ. Faculty Medicine, Kagoshima 890, Japan). *Tohoku J. Exp. Med.* 124(2):117-128; 1978.

To examine the role of epithelial dysplasia (ED) in carcinogenesis of the esophagus, the incidence of ED in 86 autopsy samples of noncancerous esophagi and its degree in 100 surgical samples of esophageal carcinoma were determined by subserial examination of the autopsy samples and by semiserial examination of the surgical samples. The prevalence, severity, distribution, and histological features of dysplasia were examined in relation to tobacco and alcohol intake in the autopsy cases and in relation to preoperative treatment in the surgical cases. Some degree of dysplasia was found in 55 of the autopsy cases. The higher grades of dysplasia were found in 17 men and in 3 women. Some correlation between the use of alcohol and cigarettes and the inci- the use of alcohol and cigarettes and the incidence and severity of dysplasia was evident but not conclusive due to incomplete data. Extensive use of alcohol appeared to correlate with more severe lesions. A definite increase in incidence and severity of dysplasia occurred with increasing age. In 13 cases, atypical active elongation of the germinal layer simulating the rete ridge was observed. Chronic inflammation, glycogenic acanthosis and hyperplasia of duct epithelium were frequently noted. In 70 of 100 surgical samples, an intimate correlation of carcinoma and dysplasia was observed, the degree of dysplasia being generally more advanced than in the autopsy samples. In 24 instances, the carcinoma was accompanied by extensive dysplasia and in 46 instances by multifocal dysplasia. Multicentric *in situ* carcinoma, frequently surrounded by severe dysplasia, was found in 19 patients. The lesion of invasive carcinoma sometimes did not show sharp demarcation from the surrounding mucosa. The effect of radiation or radiation plus bleomycin therapy on carcinoma tissue is noted. The autopsy data on the higher incidence of higher grades of dysplasia among men correlated with the documented 3.84:1 male/female ratio of death from esophageal cancer in the region. The studies on surgical samples, particularly those with no preoperative therapy, indicate that at least half of the carcinoma of the esophagus arose from the dysplastic epithelium as a precursor lesion.

8827 FIBERENDOSCOPIC MONITORIZED DILATATION OF OESOPHAGEAL STRICTURES IN CHILDREN. (Eng.) Cadranel, S.; Rodesch, P.; Peeters, J. P.; Cremer, M.; Cremer, N. (Dept. Pediatrics, Univ. Brussels, Brussels, Belgium). *Endoscopy* 9(3):127-130; 1977.

Experience with esophageal dilatation in 10 children aged 2 months to 10 yr with acquired esophageal strictures is presented. Causes included peptic stricture (3 cases), lye ingestion (2 cases), radionecrosis (1), extrinsic compression (1), congenital atresia (2), and granuloma (1). There were a total of 55 dilatations, using the classical method with rubber bougies in three patients and a newer technique using metallic olives in the remaining patients. There was one case of perforation, which occurred in a patient with caustic stricture in whom dilatation was accomplished with rubber bougies. The only other complication was laceration, occurring in a patient with congenital atresia who was treated with the metallic olives. The results obtained were judged to be excellent in one case in which metallic olives were used and good in the remainder of these cases. Good results were obtained with the classical method in the two cases without perforation. Relapses occurred in only two patients, both of whom underwent bougienage with metallic olives: in one patient with caustic stricture and in one patient with initial caustic stricture followed by relapse with peptic stricture.

STOMACH

8843 GASTRIC LESIONS IN FAMILIAL ADENOMATOSIS COLI: THEIR INCIDENCE AND HISTOLOGIC ANALYSIS. (Eng.) Watanabe, H.; Enjoji, M.; Yao, T.; Ohsato, K. (Faculty Medicine, Kyushu Univ. 60, 3-1-1, Maidashi, Higashi-Ku, Fukuoka 812, Japan). *Hum. Pathol.* 9(3):269-283; 1978.

A histologic analysis of the gastric lesions accompanying familial adenomatosis coli and an evaluation of the differences between polyps in the gastric antrum and those elsewhere in the body was conducted by x-ray and endoscopy of the stomachs of 22 patients with familial adenomatosis of the colon and rectum in 14 families. Although 7 patients did not have gastric lesions, in 15 of the patients (from 13 families), one or more types of gastric lesion was found. Gastric lesions were found in all 9 patients above the age of 30 yr and in 6 of 11 patients aged 10-29 yr. The lesions (1 in 3 cases, 3 in 1 case, 4 in 1 case, 5 in 1 case, and >5 in 9 cases) were limited to the antrum in eight cases, found elsewhere in the body in five, and present in both the antrum and other sites in two. The most common gastric lesion was the adenoma occurring in the pyloric mucosa, which was found in nine patients. Multiple lesions (maximum number, 43) were found in five cases. While there were no essential histologic differences between the gastric adenomas in the patients with familial adenomatosis coli and those in patients without the disease, the adenomas appeared at younger ages in patients with the disease and were multiple in 55.6% of these cases (versus 21.4% in patients without the disease). Fundic gland polyposis was the second most common gastric lesion in patients with familial adenomatosis coli, occurring in 6 of the 15 patients. The multiple fundic gland polyps, measuring up to 5 mm and limited to the fundic glandular mucosa, were characterized histologically by simple hyperplasia of the fundic glands. Other lesions detected included multiple gastric carcinoma (3), microcarcinoids in the pyloric mucosa (2), and multiple varioliform lesions representing erosive gastritis (2). The density of colonic adenomas was determined. Gastric lesions were found in all nine cases in the high density (innumerable adenomas) group, in four of six cases with a moderate number (500-2,000) of adenomas, and in only two of seven cases with low density of adenomas (50-200). Furthermore, extra-alimentary lesions were found in 9 of the 15 adenomatosis coli patients with gastric lesions but were present in only 1 of 7 patients without them. It is concluded that familial adenomatosis coli, Gardner's syndrome, and Turcot's syndrome are all expressions of the familial adenomatosis coli syndrome. Fundic gland polyposis seems to be the gastric lesion specific to familial adenomatosis of the colon and rectum.

8844 HUMAN NEWBORN HYPERGASTRINEMIA: AN INVESTIGATION OF PRENATAL AND PERINATAL FACTORS AND THEIR EFFECTS ON GASTRIN. (Eng.) Euler, A. R.; Ament, M. E.; Walsh, J. H. (Univ. California, Sch. Medicine, Los Angeles, CA). *Pediatr. Res.* 12(5):652-654; 1978.

Levels of gastrin secretion in newborns and adults were compared and the effect of a variety of prenatal and perinatal conditions on these levels in newborns was investigated. Serum gastrin values were determined by radioimmunoassay in 217 newborn infants and in 802 adults who had peptic ulcer disease symptoms but did not have Zollinger-Ellison syndrome or peptic ulcer disease. In six newborns, the basal acid secretion during the first 8 hr of life was measured and compared with that of 14 children with functional abdominal pain. Newborns had a median gastrin serum of 100 pg/ml while the adult median was 39 pg/ml. Mean values for newborns and adults were 135 and 49 pg/ml, resp., ($p<0.001$). No adult had gastrin levels greater than 200 pg/ml, but 29 newborns had gastrin determinations greater than 200 pg/ml, and 5 had values above 500 pg/ml. None of the 19 maternal medications studied, including oxytocin and atropine, were found to influence the newborn gastrin levels. Of 35 neonatal and maternal factors analyzed, only maternal sickle cell trait and race were shown to influence these levels. Only two mothers in the study had sickle cell trait, and their infants had gastrin levels of 1,000 and 270 pg/ml. Negro newborns had a significantly higher level of gastrin than did either Caucasian or Chicano infants, the mean log gastrin values (2.16%, 2.029%, and 1.97%, resp.) corresponding to serum levels of 147, 93, and 107 pg/ml (F=4.7, significant at 5% level). Serum gastrin levels continued to be elevated through the first 8 hr of life (mean value at 8 hr, 72 pg/ml). The basal acid secretion study demonstrated that the parietal cells of newborns secrete only small amounts of gastric acid in response to the elevated gastrin levels. Compared to the older children, the infants hyposecrete acid in response to gastrin stimulus.

8845 GASTRIC MUCOSAL CELL PROLIFERATION AND IMMUNOGLOBULIN-CONTAINING CELLS IN MENETRIER'S DISEASE.

(Eng.) Hansen, O. H.; Jensen, K. B.; Larsen, J. K.; Soltoft, J. (Bispebjerg Hosp., DK-2400 Copenhagen NV, Denmark). *Digestion* 16(4): 293-298; 1977.

The amount of immunoglobulin-containing cells in the gastric mucosa of six patients with Menetrier's disease was estimated, and the rate of gastric epithelial cell proliferation was studied in four of these patients. The area of cells containing immunoglobulin in the gastric fundic mucosa was calculated as a percentage of the total interstitial area in the lamina propria. The areas of IgA- and IgG-containing cells were within normal limits, but the area of IgM-containing cells was significantly increased (mean 9.5% compared with the normal 2.4 ± 1.8%). In three biopsies from the antrum, the area of IgM-containing cells was increased in only one. Autoradiographic studies in four patients showed that the mean labeling indices in the antral and fundic mucosa (15.2 ± 1.4 and 13.3 ± 2.3, resp.) were not significantly different from those previously reported in patients without gastric disease. The serum IgM levels were normal in all six patients. The results indicate that the number of IgM-containing cells in gastric fundic mucosa is markedly increased. This may indicate that IgM is involved in the pathogenesis of Menetrier's disease or that the increased number of IgM-containing cells is the result of a continuous antigen challenge across the much enlarged epithelial membrane.

8846 FACTORS RELEVANT TO THE OCCURRENCE, RECURRENCE AND HEALING OF CHRONIC GASTRIC ULCER: A STUDY OF AN AUSTRALIAN POPULATION.

(Eng.) Thomas, J.; Greig, M.; Shinners, J.; Piper, D. W. (North Shore Hosp., St. Leonards, 2065, New South Wales, Australia). *Rend. Gastroenterol.* 9(2):109-113; 1977.

To evaluate factors relevant to the development, recurrence, and healing of chronic gastric ulcers, 216 patients with ulcer were compared with controls matched for age, sex, and social grade. Emotional stress was measured by the frequency of 31 "major life events" in 59 patients and controls. Patients in the lower social grades experienced more of these events and had a significantly higher score for the degree of change that these events created in the patients' lives (p<0.05) than did the controls. The personality of 44 patients with ulcer was compared with that of controls, using the self-rating Eysenck Personality Inventory. Men with chronic gastric ulcer were significiantly more neurotic (p<0.01) and less extroverted (p<0.001) than their controls. Forty-three percent of 49 patients with recurrent ulcer had a positive test for urinary salicylates, compared with 24% of their controls (p<0.05). There was no significant difference in the number of positive urinary salicylate tests among 22 patients in remission and their controls. More patients than controls lived alone (p<0.01). In addition, patients reported more tension in the home than did their controls, but the results failed to reach statistical significance. Previous studies linking cigarette smoking with slower ulcer healing or with a greater incidence of recurrence could not be supported in this series. Bed rest, carbenoxolone sodium treatment, and anticholinergic drug therapy also had no influence on ulcer healing in the 54 hospitalized patients studied. Cimetidine was found to be effective in a double-blind controlled trial of 48 inpatients and outpatients.

8847 CLINICAL STUDY ON GASTRIC SECRETION WITH SPECIAL REFERENCE TO PEPSIN SECRETION.

(Eng.) Ito, K.; Inoue, M.; Noda, T.; Kuwano, K.; Takeda, H.; Kasugai, T.; *et al.* (Fukuoka Univ. Sch. Medicine, Fukuoka, Japan). *Gastroenterol. Jpn.* 13 (1):13-20; 1978.

Gastric acid and pepsin secretion were measured in groups of 10-24 patients with peptic ulcer to evaluate the preferential stimulating action of tetragastrin (4 μg/kg, i.m.), cerulein (0.2 or 0.3 μg/kg, i.m.), Histalog (1 and 2 mg/kg, i.m.), and secretin (1 clinical U/kg diluted with 15 ml of distilled water, i.v.). Tetragastrin produced a peak acid concentration and volume 30 min after administratio Acid concentration was significantly (p<0.001) increased over basal secretion. A significant (p<0.0 increase in peptic activity occurred 10 min after stimulation and then decreased gradually. Pepsin output increased 30 min after stimulation. Both doses of cerulein produced significant (p<0.05) increases in acid concentration. Increases in secretory volume and in peptic activity after cerulein injection were not significant compared with basal levels. Histalog produced a high level of peptic activity at 10 min after stimulation, which was maintained up to 30 min and was significantly (p<0.05) different from basal values. The acid concentration increased gradually, and the peak was observed 60 min after stimulation. At 60 min, the acid concentration was significantly

her than basal values ($p<0.01$ for 1 mg/kg and
.001 for 2 mg/kg Histalog). After secretin in-
tion, peptic activity increased significantly (p<
01, peak at 40 min) and acid concentration de-
ased significantly ($p<0.02$, peak at 10-30 min after
mulation). With tetragastrin or cerulein as stimu-
t, the increase in peptic activity depended on
increase in acid secretion. Since only a
ght increase in pepsin secretion was seen when
rulein was used, the authors conclude that ceru-
n stimulates parietal cells but will not stimu-
e chief cells. The increased peptic activity
lowing the increase of acid concentration may be
sed on "wash-out" action caused by increase of
d secretion after stimulation. The secretory
tern observed when Histalog was the stimulant
dicates that Histalog stimulates the chief cells
dependent of acid secretion. Secretin also
imulates chief cells. The results indicate that
stalog is a more adequate stimulant for pepsin
cretion than is gastrin or cerulein.

48 DOUBLE-BLIND STUDY OF CARBENOXOLONE IN GASTRIC ULCER AND EROSIONS. (Eng.) Leh-
la, J.; Karvonen, A. L.; Tunturi-Hihnala, H.
niv. Central Hosp., SF-90220 Oulu 22, Finland).
n. Clin. Res. 10(1):19-23; 1978.

e value of carbenoxolone in the treatment of
stric ulcers and erosions was studied, and its
fects on gastric acid secretion and on serum
strin levels were investigated. In a double-
ind study, 20 patients with chronic gastric
cer and 20 patients with gastric erosions re-
ived either placebo or carbenoxolone sodium (50
) during 6 weeks. All patients also received
tacids and were placed on an anti-ulcer diet.
stroscopy was carried out at the onset of treat-
nt and 3 and 6 weeks after the start of treat-
nt. The ulcers of five patients receiving car-
noxolone healed during the 6-week treatment
riod, whereas ulcers in four patients in the
acebo group healed during this period. Erosions
seven patients receiving carbenoxolone healed
ring the 6-week period, and erosions in 11
tients in the placebo group healed during
is period; in two patients the erosions that
d healed after 3 weeks' treatment recurred
6 weeks. There were no significant dif-
rences at any time during the study in the
aling of gastric ulcers or erosions between the
tients receiving placebo and those receiving car-
noxolone. However, after 3 weeks' treatment,
e patients receiving carbenoxolone were sub-
ctively in better general condition than were the
tients receiving placebo (difference statistical-
significant at the 5% level). No significant
anges in the maximal acid output or in the serum
strin levels were seen in the ulcer or erosion
tients before and after carbenoxolone or placebo
eatment. No cardiovascular side-effects were
ident during carbenoxolone treatment, although
e patient required potassium supplementation.
e small dosage may explain the negligible effect
carbenoxolone on the healing of the gastric
sions and on the low incidence of side-effects
this study.

8849 EFFECT OF ULCER HEALING ON THE PROGNOSIS OF CHRONIC GASTRIC ULCER: FOUR-YEAR FOLLOW-UP. (Eng.) Piper, D. W.; Shinners, J.; Greig, M.; Thomas, J.; Waller, S. L. (Royal North Shore Hosp., Sydney, Australia). *Gut* 19(5):419-424; 1978.

To determine the influence of complete healing at the time of discharge from the hospital on the prognosis of chronic gastric ulcer, 83 patients were followed up for 4 yr after an admission to hospital with a chronic gastric ulcer proven by radiology (index ulcer). The index ulcer healed completely in 50 patients, but was unhealed at the time of discharge in the other 33. Significantly fewer patients whose index ulcer was healed compared with those whose ulcer was unhealed at discharge had had a recurrence by 1 ($p<0.05$), 2, 3, and 4 yr ($p<0.01$) of follow-up. Moreover, the rate of recurrence was significantly greater for those patients with an unhealed index ulcer compared with those with a healed index ulcer ($p<0.05$), and by the end of the 4-yr period, 61% of patients with unhealed compared with 26% of those with healed index ulcers had had a recurrence. Patients over the age of 60 yr with unhealed index ulcers had a significantly poorer prognosis than those of similar age whose index ulcer was healed at discharge ($p<0.025$). The sex of the ulcer patient did not significantly influence ulcer recurrence. Large ulcers ($>57\ mm^2$) were less often healed on initial discharge and were more frequently associated with recurrence at 1 ($p<0.05$), 2 ($p<0.025$) 3, and 4 yr ($p<0.01$) than were smaller ulcers ($\leq 57\ mm^2$). Heavy intake of analgesics adversely influenced the course of patients whose ulcer was unhealed ($p<0.05$), but did not alter the recurrence rate in those whose ulcer was healed. Ulcer recurrence was not influenced by smoking habits or by alcohol consumption.

8850 COMPOSITION OF THE ALKALINE COMPONENT OF HUMAN GASTRIC JUICE: EFFECT OF SWALLOWED SALIVA AND DUODENO-GASTRIC REFLUX. (Eng.) Okosdinossian, E. T.; El Munshid, H. A. (Dept. Physiology, Univ. Khartoum, P.O. Box 102, Khartoum, Sudan). *Scand. J. Gastroenterol.* 12(8):945-950; 1977.

To further substantiate the two-component hypothesis of gastric secretion (i.e., that gastric juice contains an acid and an alkaline component), the composition of alkaline gastric juice from four achlorhydric or hypochlorhydric patients with vitiligo and one patient with pernicious anemia was studied. Saliva swallowing was alternately allowed or prevented, and in this way the contribution of swallowed saliva to the pure alkaline component was assessed. The volume refluxed from the duodenum was estimated to assess the contribution of duodenal juice. Reflux was absent in one patient and negligible in another, while in the remaining three patients, the mean pyloric reflux amounted to no more than 8% of the observed volume. Swallowed saliva had a significant diluting effect on both the Na^+ and Cl^- concentrations ($p<0.01$ and $p<0.001$, resp.), but the K^+ concentration was significantly increased in the alkaline gastric aspirate ($p<0.05$). The composition of alkaline gastric juice, free to an appreciable extent of salivary contamination, was relatively constant. The results are consistent with the two-component hypothesis of gastric secretion.

8851 GASTRIC VOLVULUS UNASSOCIATED WITH HIATAL HERNIA. (Eng.) Pillay, S. P.; Angorn, I. B.; Baker, L. W. (Dept. Surgery, Univ. Natal, Durban, South Africa). *S. Afr. Med. J.* 52(22): 880-885; 1977.

Clinical findings in 16 patients with gastric volvulus not associated with hiatal hernia are reported, and two case reports are presented. Of 10 patients who presented with volvulus unrelated to previous trauma, 3 presented with an acute volvulus, which constituted an abdominal emergency, with either obstruction or strangulation of the stomach, and required surgery. Of the six patients with relevant antecedent trauma, five presented with acute volvulus. Both deaths in this series were associated with an acute presentation. Two patients, who were both in the group with antecedent trauma, developed gangrene of part of the stomach wall, which resulted in the death of one patient before emergency surgery could be performed. All 16 patients presented with abdominal pain and vomiting, but a third common observation in gastric volvulus, i.e., inability to pass a nasogastric tube, was absent in all cases. Severe hematemesis due to gangrene or erosive gastritis occurred in three patients. Contrast studies of the upper gastrointestinal tract confirmed the diagnosis in 14 patients. Congenital diaphragmatic abnormalities were present as a causative factor in four patients. Diaphragmatic defects in the six patients with antecedent trauma were due to blunt or penetrating diaphragmatic injury, which preceded the admission for volvulus by intervals of 6 months to 4 yr. Alimentary tract lesions in the esophagus (1), stomach (2), and duodenum (1) were detected in four patients. In one patient, both a congenital defect of the hemidiaphragm and a gastric ulcer were present. Idiopathic volvulus was diagnosed in four cases. Among the patients without previous trauma, two with mesenterio-axial volvulus responded well to dietary modification. Plication of a congenital eventration of the left hemidiaphragm, gastropexy, and subphrenic transposition of the colon were associated with a good result in one patient, but volvulus recurred after gastropexy and colon transposition in a second patient, in whom a previously unrecognized gastric ulcer was discovered. The presence of an associated gastric ulcer was overlooked in another patient, in whom secondary gastric volvulus was presumed to be due to eventration of the left hemidiaphragm. In three patients with traumatic volvulus, thoracotomy exploration permitted easy reduction and the repair of diaphragmatic defects. Exploration via laparotomy in two patients was associated with great difficulty in dividing intrathoracic adhesions, reducing the volvulus and repairing the diaphragm. The rational management of gastric volvulus involves recognition that the condition may be idiopathic or secondary, treatment of associated conditions on their merits, awareness of diaphragmatic injury as a possible causative factor, and the use of gastropexy and subphrenic colonic displacement where indicated to prevent recurrence.

STOMACH

Peptic Ulcers

902 VALUE OF THE ^{14}C-GLYCOCHOLATE TEST: INVESTIGATIONS IN PATIENTS WITH BILLROTH-I-RESECTED STOMACHS. (Ger.) Adlung, J.; Raguse, .; Grazikowske, H. (I. Medizinische Klinik, Medizinische Hochschule Lubeck, Kronsforder Allee 71/73, -2400 Lubeck, W. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 38(1):2-7; 1978.

he ^{14}C-glycocholate exhalation test was performed n 34 healthy subjects, 9 patients with Billroth II astric resections and various gastrointestinal iseases (fatty degeneration of the liver, hronic pancreatitis, pernicious anemia, dumping yndrome, jaundice, cholelithiasis, cholestasis, alabsorption, and afferent loop syndrome), and 32 ubjects with Billroth II gastric resections but ithout any gastrointestinal diseases. The ^{14}C-lycocholate was administered as a p.o. dose of 0 μCi of labeled compound (specific activity, 10-0 mCi/mmol). All 41 patients had undergone gastric resection for benign ulcer; the glycocholate est was performed 3-4 weeks after gastric reection in 15 cases and 2-40 yr after surgery in 6 cases. The $^{14}CO_2$ exhalation was normal in the ealthy controls and in the 32 subjects with Billroth II gastric resections without gastrointestinal iseases, but it was significantly and pathologically increased ($p<0.001$) in 7/9 patients with illroth II gastric resections and gastrointestinal iseases. According to the hypothesis that the deconjugation of bile salts is possible only by bacterial enzymes, the pathological test result found in the seven patients can be explained only by the presence of bacteria in the upper segment of the intestinal tract or by the loss of bile salts in these patients.

8903 POSTOPERATIVE ANASTOMOTIC ULCER: A REPORT OF 50 CASES. (Fre.) Boiselle, J.; de Montalier, H. (Hopital Bichat, 170, boulevard Ney, 75018 Paris, France). *Ann. Chir.* 31(8):685-692; 1977.

Postoperative ulcers (termed peptic ulcers or anastomotic ulcers) were studied in 50 patients who had previously undergone ulcer surgery. The average delay in appearance of the second ulcer was as long as 30 yr but was only 4 yr for those with previous gastrectomies and 12 yr for those with previous gastroenterostomies. In 34 patients, the anastomotic ulcers could be attributed to technical errors in the initial surgery, usually incomplete vagotomies (11) or insufficient gastrectomies (21). Patients with previous gastroenterostomies underwent a vagotomy and antrectomy or 2/3 gastrectomy as treatment of the second ulcer. Vagotomies were performed on patients with previous gastrectomies and new vagotomies and antrectomies were done for patients who had initially undergone vagotomies and drainage. Zollinger-Ellison syndrome was found in two patients who had initially been misdiagnosed; they were treated by total gastrectomies. In three patients who developed peptic ulcers after bypass surgery for pancreatic tumors, a modification of the bypass circuit and a new gastroenterostomy were performed. Postoperative mortality was 8/50 but second recurrences occurred in only survivors. It is stressed that successful ulcer treatment must reduce gastric secretion.

8904 THE DEVELOPMENT OF MUCOSAL CHANGES AFTER GASTRIC SURGERY FOR ULCER DISEASE. (Eng.)

Janunger, K. G.; Domellof, L.; Eriksson, S. (Univ. Hosp., Umea, Sweden). *Scand. J. Gastroenterol.* 13 (2):217-223; 1978.

To investigate the relationship between morphological changes occurring after gastric surgery and factors such as age, sex, and time of follow-up, and between morphological changes and the development of stump carcinoma, the development of morphological changes in the body mucosa after partial gastrectomy for ulcer disease was studied early (within 3 yr) and late (10-24 yr) postoperatively in 306 patients. Forty-one patients were studied early after Billroth I resection, 14 early after Billroth II resection, 79 late after Billroth I resection, and 172 late after Billroth II resection for gastric or duodenal ulcer. All patients underwent gastroscopy and six forceps biopsies. When agreement between the different biopsies in the same patient was studied, it was not possible to evaluate 19% of the biopsies for technical reasons. On the average, atrophy was found in 4.4 ± 1.5/6 biopsies. The corresponding figures were 4.6 ± 1.5 for acute gastritis, 4.4 ± 1.5 for chronic gastritis, 2.9 ± 1.6 for cystic dilatation, and 1.8 ± 1.2 for intestinal metaplasia. Duodenal ulcer patients and gastric ulcer patients developed mucosal atrophy, cystic dilatation of the gastric glands, and intestinal metaplasia to a similar extent. There was a significantly greater incidence of cystic dilatation of the gastric glands ($p<0.001$) after Billroth II than after Billroth I resection in the patients in whom the biopsy was taken late after surgery. In the early postoperative Billroth I group, an increased incidence in mucosal atrophy, severe chronic gastritis, and intestinal metaplasia were found with increasing age. However, no difference was found in the late postoperative group, and sex did not affect mucosal changes. There were no further relationships between age or type of operation on the development of mucosal changes. Mucosal atrophy, chronic gastritis, and intestinal metaplasia are regarded to be possible features of malignant transformation. If this concept is true, the present findings may explain why stump carcinoma is frequently reported with an incidence that is independent of preoperative ulcer disease or anastomotic procedure.

8905 GASTROESOPHAGEAL SPHINCTER PRESSURE AND SERUM GASTRIN STUDIES FOLLOWING FOOD INTAKE BEFORE AND AFTER VAGOTOMY FOR DUODENAL ULCER. (Eng.)

Csendes, A.; Oster, M.; Brandsborg, O.; Moller, J.; Brandsborg, M.; Amdrup, E. (Hospital J. J. Aquirre, Santiago, Chile). *Scand. J. Gastroenterol.* 13(4):437-441; 1978.

The interrelationship between serum gastrin concentration and gastroesophageal sphincter pressure (GESP) was studied in the basal state and after food stimulation in six patients with duodenal ulcer, six patients who had undergone parietal cell vagotomy (PCV), six patients who had undergone selective gastric vagotomy with drainage (SGV + D), and six patients who had undergone SGV and antrectomy (SGV + A). No correlation between GESP and the serum gastrin concentration was observed in the basal state. Immediately after food ingestion, a sustained rise in GESP occurred in the duodenal ulcer patients, which lasted at least up to the end of the experiment. GESP after food ingestion at 60 to 100 min was significantly higher than basal values ($p<0.05$). No increase in GESP occurred in any of the operated patients; in fact, a slight decrease occurred. This decrease was not significantly different from basal values, but was significantly different from the GESP values for duodenal ulcer patients from 60 to 120 min after food ingestion ($p<0.01$). Patients with SGV + D showed basal serum gastrin concentrations that were significantly higher than those in duodenal ulcer patients or patients with SGV + A ($p<0.01$), but not different from those of the PCV patients. After food ingestion, an increase in the serum gastrin concentration occurred in all patients with duodenal ulcer as well as in patients after PCV or SGV + D. Patients with SGV + A showed no increase in gastrin level at any period after food ingestion. The mean gastrin concentration was significantly lower at any period of time compared with the values for all other groups ($p<0.01$). Patients with SGV + D showed significantly greater serum gastrin concentration than did duodenal ulcer patients at 15, 60, and 120 min after food ingestion ($p<0.05$). The increase in gastrin level lasted in all groups for at least 120 min after food intake. The results do not suggest that the serum gastrin concentration and extrinsic vagal innervation in the resting state play a significan role in the maintenance of the tone of the gastroesophageal sphincter. After food ingestion, an interaction may occur between intact vagal innervation and a rise in serum gastrin concentration to obtain an adequate rise in GESP.

8906 PROXIMAL SELECTIVE VAGOTOMY: INTRAOPERATIVE CONTROL OF COMPLETENESS. (Ger.)

Jacobs, G.; Baumgartner, H.; Feifel, G.; Martinoli S. (Chirurgische Klinik A, Universitat Dusseldorf, D-4000 Dusseldorf, W. Germany). *Langenbecks Arch. Chir.* 345:217-222; 1977.

The intraoperative control of the completeness of proximal selective vagotomy (PSV) by the modified vagomotor electrotest according to Burge in the treatment of peptic gastroduodenal ulcer is described. The vagomotor electrotest is based upon the loss of motility of the denervated part of the stomach during electrical stimulation of the vagal

runks. The denervated part of the stomach is
eparated from the antrum by a soft clip, and this
art of the stomach is filled with air to a pres-
ure of 60-80 mm H_2O and then connected to a pres-
ure recorder. The PSV is complete if the elec-
rical stimulation of the denervated part of the
tomach causes a pressure rise. The electrotest
as performed in 728 patients; the results were
valuable in 699. Simultaneous pH measurements,
erformed in 678 cases, were evaluable in 441
ases only. The pH test was positive in 68 cases;
he results of the pH test and electrotest coin-
ided in 208 cases. Incomplete PSV was detected
nly by the pH test in 22 cases, while the pH test
as negative in 221 cases in which the electro-
est demonstrated incomplete PSV. The findings
ndicate that the electrotest should always be
erformed during PSV, regardless of how experienced
he surgeon is.

SMALL INTESTINE

8926 ANGIOGRAPHIC DIAGNOSIS OF INTESTINAL CARCINOID TUMORS. (Ger.) Bardach, G.; Fasching, W.; Raff, M. (Abt. Rontgen, II. Chir. Univ.-Klinik Wien, Spitalgasse 23, A 1097 Vienna, Austria). *Roentgenblaetter* 31(3):155-159; 1978.

Two angiographically documented cases of intestinal carcinoid tumor are described. Carcinoid tumor of the terminal ileum with hepatic metastases was found in the first case and cecal carcinoid tumor without distant metastases in the second. A fibroplastic reaction was found in the mesentery in both cases. The carcinoid tumor in the second patient was strikingly hypervascularized, while most of the primary carcinoid tumors so far described in the literature were hypovascularized. The fibroplastic reaction of the mesentery was indicative of lymph node metastases in both cases. Differentiation between small intestinal carcinoid tumor and Crohn's disease is difficult and often impossible, because mesenteric adhesions seen in Crohn's disease may imitate the typical fibroplastic reaction seen in cases of carcinoid tumor.

8927 ANGIOGRAPHY IN THE DIAGNOSIS OF ILEOCECAL TUBERCULOSIS. (Eng.) Herlinger, H. (St. James' Univ. Hosp., Leeds, England). *Gastrointest. Radiol.* 2(4):371-376; 1978.

To illustrate the use of angiography in the differentiation of ileocecal tuberculosis from Crohn's disease, two case studies are presented. The young women patients presented with pyrexia, abdominal pain, and weight loss. Each had a tender right iliac fossa mass and normal chest x-ray. Barium studies in both patients were consistent with Crohn's disease, showing in case 1, a grossly ulcerated cecum and an irregularly narrowed terminal ileum surrounded by a soft tissue mass and, in case 2, contraction and ulceration of the cecum with the terminal ileum slightly dilated with retained flui material. Very abrupt demarcation between areas of normality and disease were considered unusual. Angiographic findings (including intense vascularity, small artery irregularity, an intensified venous phase, and in case 1, a positive zoning sign) were typical of Crohn's disease. However, i both cases, an enlarged and hyperemic mesenteric lymph node close to the cecum was clearly shown in the arterial and venous phases of the angiograph. Resection and anastomosis was carried out successfully in both cases and confirmation of the ileocecal tuberculosis was obtained at biopsy of the bowel and regional lymph nodes. The incidence of ileocecal tuberculosis, particularly in underdeveloped countries, the similarities and contrast between ileocecal tuberculosis and Crohn's disease the importance of accurate diagnosis, and diagnostic problems are discussed. The angiographic appearance demonstrated in these two patients is a useful diagnostic indicator of tuberculosis etiology. If the findings are confirmed in a larger group, medical antituberculosis therapy might be started without prior biopsy surgery.

8928 EFFECT OF CODEINE PHOSPHATE, LOMOTIL, AN ISOGEL ON ILEOSTOMY FUNCTION. (Eng.) Newton, C. R. (St. Mark's Hosp., London, England). *Gut* 19(5):377-383; 1978.

The effect on ileostomy output of codeine phosphat (C), Lomotil (L), and Isogel (I) was studied in 18 ileostomists living a normal life at home. During a 3-day test period, five subjects took C (60 mg, t.i.d.), seven took L (diphenoxylate, 2.5 mg and atropine, 0.025 mg/tablet, 2 tablets t.i.d.), and

x took I (Ispaghula husk, 15 ml or 6 g, t.i.d.).
n one of the test days, a mouth-to-stoma transit
tudy was conducted. Total ileostomy output and
utput of water were significantly increased by I
+250 g/24 hr, $p<0.01$), significantly decreased by C
-236 g/24 hr, $p<0.05$), and decreased by L (-57 g/24
-). The mean weight of fecal solids was signifi-
antly increased by I (19 g/24 hr, $p<0.01$) but was
ot significantly changed by C or L. The proportion
f fecal solids was unchanged by I or L but was sig-
ificantly increased by C (2% increase, $p<0.05$).
he ileostomy outputs of sodium and potassium in-
reased ($p<0.01$) in response to I, but decreased in
esponse to C and L ($p<0.05$) without change in their
oncentrations. The output of fecal fat rose signifi-
antly in response to C (from 6.1 to 9.6 g/24 hr, p<
.05). The total ileostomy output ranged from 383
o 1,335 g/24 hr in 16 of the patients. Two patients
n L had total ileostomy outputs greater than 3 kg/
4 hr. The effect of L in these patients was simi-
ar to its effect in patients with lower total out-
uts. The excessive ileostomy output was related to
xtensive ileal resection in these patients. The
outh-to-stoma transit study showed no significant
hanges due to I or L. In the patients using C, the
ransit was slower, although not statistically sig-
ificant, in four of the five subjects. The possi-
le reasons for this negative correlation between C
nd transit time are discussed along with the rea-
ons why L appears to be less effective than C in
he present study. The authors conclude that C and
are effective in reducing the ileostomy loss of
ater and electrolytes, while I increases their loss
nd can aggravate depletion in patients with exces-
ive fluid effluents. The increase in fecal fat
ssociated with C use suggests that it should be
topped before collecting samples for fecal fat
eterminations.

929 RADIOLOGIC EVALUATION OF THE CONTINENT (KOCK) ILEOSTOMY.

(Eng.) Montagne, J.
.; Kressel, H. Y.; Moss, A. A.; Schrock, T. R.
Univ. California Sch. Medicine, San Francisco, CA).
diology 127(2):325-329; 1978.

he surgical procedure for constructing an ileos-
omy with an ileal reservoir, a continent (Kock)
leostomy, and the radiographic features of normal
nd malfunctioning continent ileostomies are de-
cribed. In the surgical procedure, approximately
0 cm of ileal loop is sutured to itself, the
owel is cut, and the ileal loop is opened. The
eservoir is manufactured by folding and suturing
he distal part of the loop to the proximate end.
nipple valve is created by intussusception of
-5 cm of distal ileum into the lumen of the re-
ervoir. Radiographically, the normal ileal re-
ervoir is usually seen as a slightly lobulated
as-filled structure in the middle or right side
f the pelvis. Unemptied, the reservoir may simu-
ate a pelvic abscess on plain film. Using a con-
rast agent administered p.o. or retrograde by
eans of an ileostomy enema, the oval shape of the
leal reservoir and the fine, feathery, nonedema-
ous appearance of the ileal mucosa in the reser-
oir and the proximal ileal segment are seen. The
erminal invaginated ileal segment resembles an inverted nipple protruding into the pouch. This normal finding should not be mistaken for a mass or intussusception. Absence of this filling defect indicates prolapse of the nipple valve out of the nipple pouch, and surgical revision is required. The site of a small bowel obstruction can be determined by means of either small bowel follow-through examination or an ileostomy enema administered retrograde with reflux into the proximal ileum. When abscess formation is suspected, an abdominal radiograph should be made after the reservoir has been drained; the abscess will remain visible in the emptied reservoir. If anastomotic breakdown is suspected, a radiographic examination using water-soluble, iodinated contrast medium administered retrograde through the ileostomy will demonstrate extravasation of contrast medium outside the reservoir. Nonspecific ileitis and recurrent granulomatous disease of the ileal reservoir or proximal ileum show radiographically irregular, thickened, blunted mucosal folds in the pouch and ileum. Endoscopy and mucosal biopsy may be needed to detect a recurrence of Crohn's disease.

8930 DUODENAL MUCOSAL DAMAGE ASSOCIATED WITH CHRONIC USE OF ANTI-INFLAMMATORY DRUGS.

(Eng.) Tanaka, M.; Uchiyama, M.; Ikeda, S. (Higashi-Kunisaki Koiki Hosp., 1456 Shimoharu, Aki-cho, Higashi-Kunisaki-gun, Oita 873-02, Japan). *Endoscopy* 9(3):136-139; 1977.

Three cases of multiple duodenal erosions or ulcers associated with the long-term use of anti-inflammatory agents are presented. The first patient was a 58-yr-old man who had ingested various analgesics (ibuprofen, diclofenac sodium with aminopyrin, phenacetin, and caffeine; buffered aspirin with aminopyrin, phenacetin, and caffeine; and buffered aspirin with aminopyrin, phenacetin, and caffeine) for various periods over 15 months for spastic muscle aches associated with quadriplegia due to traumatic cervical cord injury. The patient developed massive hematemesis and melena, which ceased after 10 days of treatment; this consisted of withdrawal of p.o. analgesics, bland diet, and antacids. The bleeding was from multiple large ulcers involving the bulbar and postbulbar portion of the duodenum. The antrum also contained a few erosions. The second patient was a 67-yr-old man who had taken 2.0 g of buffered aspirin p.o. in addition to a rectal dose of 50 mg of indomethacin daily for 10 months to reduce arthralgia. He presented with epigastralgia accompanied by hematemesis. Endoscopy revealed diffuse superficial gastritis with multiple hemorrhagic erosions, which were most numerous in the antrum. Shallow, actively bleeding erosions were seen in the duodenum. The third patient, a 47-yr-old woman who had taken ibuprofen (800 mg/day, p.o.) and indomethacin (50 mg/day, rectally) for 10 weeks, presented with hematemesis. Endoscopy showed extensive erosive gastritis with shallow ulceration. Marked congestion, friability and multiple shallow ulcers were seen in the duodenal bulb. This report emphasizes the possibility of duodenal mucosal injury related to anti-inflammatory agents.

Malabsorption

947 THE ROLE OF VARIOUS CEREALS IN COELIAC DISEASE. (Eng.) Anand, B. S.; Piris, J.; ruelove, S. C. (Radcliffe Infirmary, Oxford, Eng- and). *Q. J. Med.* 47(185):101-110; 1978.

he effects of four different cereals (60 g/day, .o., for 1 month) in celiac disease were assessed n celiac patients in remission on a gluten-free iet. Jejunal biopsy in all five patients who re- eived barley revealed definite evidence of his- ological damage, yet none of the patients exper- enced symptoms. The mean surface to volume ratio efore barley consumption was 30.48, and this de- reased considerably after barley consumption in ll but one patient who had a low ratio to start ith. There was a fall in disaccharidase levels n all five patients ($p<0.05$ for mean levels of ucrase, lactase, and maltase). Two patients re- eived rye. In the first patient, the jejunal bi- psy taken before rye consumption showed partial illous atrophy, whereas the other patient had a ear-normal jejunal mucosa at the start of the tudy. After rye consumption, the biopsy showed n almost complete loss of villi, crypt hypertrophy, nd an increase in chronic inflammatory cells in he lamina propria. The surface to volume ratio ecreased from 22.19 to 12.79. The second pa- ient developed diarrhea, nausea, abdominal dis- omfort, and irritability after consuming rye for weeks. The villi were short and broad, there as crypt hyperplasia with an increase in the num- er of mitotic cells, the inflammatory infiltrate ad increased, and the superficial epithelial cells ere flat with loss of polarity of the nuclei. he surface to volume ratio decreased from 48.64 o 29.20. All three disaccharidases decreased in iopsy specimens from both patients. Neither of wo patients who consumed maize and none of three ho consumed rice developed symptoms or histo- ogical abnormalities in the jejunum. The results ndicate that barley and rye products should be liminated from the diets of patients with celiac isease.

948 VARIATIONS IN THE BLOOD AMINO ACID LEVELS IN CHILDREN WITH CELIAC DISEASE FOLLOWING PECIAL DIET THERAPY. (Ita.) Balli, F. (Istituto i Clinica Pediatrica dell'Universita di Modena, odena, Italy). *Minerva Pediatr.* 29(37):2255-2257; 977.

ata concerning 13 children (aged 8 months-6 yr) with eliac disease are presented. The symptoms included iological and clinical signs of malabsorption when he diet contained gluten, typical histological bnormalities of the duodenal-jejunal mucosa, and linical and biological remission when gluten was ithdrawn from the diet. All of the children had rade III atrophy of the jejunal mucosa. The phase f the disease was determined by the gas chromato- raphy profile of the levels of free amino acids in heir sera. The patients' diets were changed: gluten and lactose were excluded, and an enzymatic hydrolysate of casein was added. Children <1 yr old received 5-6 protein/kg, 12-15 g carbohydrates (glucose, fructose from honey, starch from rice, corn, tapioca, and sucrose from fruit)/kg, and 2.5-3 g of fat/kg daily. Before the diet therapy, the levels of the essential amino acids (particularly valine, isoleucine, lysine, and phenylalanine) were low, while the nonessential amino acids (particularly glycine) were elevated. After only 1 month of diet therapy, while clinical results were not yet evident, there was an increase in the blood levels of several of the essential amino acids (approximate average values were: valine increased from 2 to 5 mg%, isoleucine from 1 to 2 mg%, phenylalanine from 3 to 4 mg%, and lysine from 2 to 4 mg%), while leucine decreased from 3 to 2.5 mg%; there was a decrease in the glycine level (from 4 to 2 mg%). The glycine/valine ratio changed from 2.06 before treatment to 0.47 (normal value is <1) after 1 month of diet therapy. Early clinical improvements followed (changes in mood and in psychomotor and neurological functions). The results demonstrate the correlation between normalization of protein metabolism and early improvement in psychomotor and neurological functions.

8949 FUCOSIDOSIS AND I-CELL DISEASE: A FINE-STRUCTURAL AND SILVER-STAINING STUDY OF ABNORMAL INCLUSION BODIES IN SMALL-INTESTINAL CELLS. (Eng.) Ginsel, L. A.; Cambier, P. H.; Daems, W. T. (Lab. Electron Microscopy, Univ. Leiden, Rijnsburgerweg 10, Leiden, Netherlands). *Virchows Arch.* [*Cell Pathol.*] 27(2):99-117; 1978.

Small intestinal cells of a 14.5-yr-old patient with fucosidosis, a 9-month-old patient with I-cell disease, and three control children (ages 2.5, 9, and 11 yr) with suspected familial celiac disease were studied, with special attention given to the fine structure and silver-staining patterns of abnormal, lysosome-like inclusion bodies. Abnormal inclusion bodies were found in the small intestinal cells of both patients. The silver-proteinate affinity of the stored material in the greater part of these abnormal inclusion bodies demonstrated the presence of mucopolysaccharides and/or glycoproteins. The lamellar structures regularly observed in these vacuoles indicated the storage of lipid-like material. Significantly enlarged lysosome-like bodies in the absorptive cells of these two patients showed the same silver-stain affinity as the Golgi apparatus, the apical vesicles and tubules, and the cell coat on the microvilli of the absorptive cells. Fusions between the apical vesicles and tubules and the lysosome-like bodies, all of which had identical silver-proteinate affinity, were also observed. These findings suggest a regulatory function of the lysosome-like bodies in the transport or secretion of cell coat material that might be of the crinophagic type.

The presence of many abnormal vacuoles in the macrophages of both patients and in the endothelial cells of the patient with fucosidosis indicated that these cells too are involved in lysosomal storage. Numerous abnormal inclusion bodies in the fibroblasts in the small intestine of the patient with fucosidosis were also observed. Abnormal inclusions were also found in the fibroblasts in the small intestine of the patient with I-cell disease. The patient with I-cell disease also showed normal inclusion bodies in peripheral blood lymphocytes and cultured skin fibroblasts. The above findings are compatible with the concept of inborn lysosomal storage disease, which explains the accumulation of material in lysosomal storage vacuoles as a consequence of inadequate degradation due to a deficiency of lysosomal hydrolytic enzymes.

8950 COWS' MILK PROTEIN-SENSITIVE ENTEROPATHY: COMBINED CLINICAL AND HISTOLOGICAL CRITERIA FOR DIAGNOSIS. (Eng.) Iyngkaran, N.; Robinson, M. J.; Prathap, K.; Sumithran, E.; Yadav, M. (Dept. Pediatrics, Univ. Malaya, Kuala Lumpur, Malaysia). *Arch. Dis. Child.* 53(1):20-26; 1978.

Diagnostic criteria for cows' milk protein-sensitive enteropathy were assessed in 15 infants with diarrhea, all of whom were suspected of having this type of enteropathy. Cows' milk was eliminated from the diet for 6-8 weeks. A jejunal biopsy was then carried out, and a repeat biopsy was performed 24 hr after challenge with cows' milk formula. The biopsy appearance was classified on the basis of four parameters: villous morphology under the dissecting microscope, villous/crypt height ratio, epithelial cells, and cellular infiltration. In four infants, no significant alteration was noted in the jejunal mucosa 24 hr after the reintroduction of cows' milk; these infants continue to thrive on cows' milk formula. The biopsy in the remaining 11 patients was considered to be moderately abnormal in 8 and severely abnormal in 3, although the prechallenge biopsy was normal in 4 and mildly abnormal in the other 8. Seven of the 11 infants developed symptoms at 0.5 hr to 2 weeks after challenge, but the other 4 have not yet developed symptoms and are making satisfactory clinical progress on a cows' milk formula. The following set of criteria for cows' milk protein-sensitive enteropathy are proposed: (a) clinical disease (diarrhea with or without vomiting) while receiving cows' milk protein, (b) clinical improvement on a diet free of cows' milk protein, (c) normal or mildly abnormal jejunal histology 6-8 weeks after symptoms subside, and (d) histological relapse, with or without clinical relapse, after reintroduction of cows' milk protein.

8951 FIRST OBSERVATION OF COLLAGEN SPRUE IN AN INFANT. (Fre.) Mougenot, J. F.; Martin, E.; Lemoine, P.; Boccon-Gibod, L.; Fontaine, J. L.; Navarro, J.; *et al.* (Hopital Trousseau, 28, rue du docteur A. Netter, F 75571 Paris Cedex 12, France). *Nouv. Presse Med.* 6(30):2689-2690; 1977.

An unusual case of collagen sprue in a 17-month-old infant is reported. The symptoms of sprue followed a bout of infectious diarrhea that affected the whole family, but only this child developed complications. The complications appeared to consist of protein exudative enteropathy, electrolyte depletion with secondary hyperaldosteronism, and intestinal dyskinesia causing repeated partial occlusion. These symptoms are similar to those observed in collagen sprue in adults with the difference that the intestinal lesions (ulcerous ileitis, collagen infiltration of the intestinal mucosa) were more distal in the infant. A gluten-free diet and a diet without allergens failed to improve the condition. An ileal bypass was performed, but the intestinal fluid exudate persisted and p.o. corticotherapy was initiated followed by i.v. steroids. Only slight improvement occurred and the child died at the age of 3.5 yr after a succession of staphylococcal infections resistant to antibiotics. It was thought that the disease may have been related to an immunopathological reaction to microbial antigens of the intestinal flora. A lymphoblast transformation test with coli bacillus antigens was positive, but other tests for immune deficiencies or allergies were negative.

LARGE INTESTINE

960 PSEUDOMEMBRANOUS COLITIS: 10 CASES.
(Fre.) Tubiana, J. M.; Nordlinger, D.;
hermet, J.; Douvin, D.; Lecomte, A. (Hopital Saint-
ntoine, 184, rue du Faubourg Saint-Antoine, 75571
aris Cedex 12, France). *J. Radiol. Electrol. Med.*
ucl. 58(12):811-818; 1977.

en case histories are presented of patients who
eveloped pseudomembranous colitis after treatment
ith antibiotics. Lincomycin (1.5-2 g/day, p.o. or
-2.4 g/day, i.v. or i.m.) and ampicillin (2 g/day,
.o. or 3-12 g/day, i.v.) were involved in five
ases each (once in association with each other),
taphlomycin (2 g/day, p.o.) in one case, and clin-
amycin (1.2 g/day, p.o.) and thiophenacol (1.5
/day, i.m.) each once in association with linco-
ycin or ampicillin, resp. Duration of treatment
anged from 4-40 days but was usually 5-10 days.
he initial clinical sign was diarrhea in every
ase. Rectoscopy showed a false membrane composed
f fibrin, mucous, leukocytes, necrotic cells, and
pithelial debris. The colon glands were hyper-
rophied and hypersecretory. The characteristic
ppearance of the colon on barium x-ray revealed
iffuse "thumbprint" lacunae, 2-4 mm in diameter,
hich projected slightly into the lumen of the
ntestine when profile x-rays were taken. The
acunae were scattered throughout the left colon
ith intervals of healthy mucosa between them. The
-ray signs regressed, often within a month, after
he antibiotics were discontinued.

961 CEPHALOSPORIN-ASSOCIATED PSEUDOMEMBRANOUS
COLITIS. (Eng.) Hutcheon, D. F.; Milli-
an, F. D.; Yardley, J. H.; Hendrix, T. R. (Johns
opkins Hosp., 601 North Broadway, Baltimore, MD
1205). *Am. J. Dig. Dis.* 23(4):321-326; 1978.

he association of pseudomembranous colitis (PC)
ith the use of the antibiotic, cephalosporin,
as investigated in three cases. In cases 1 and
, the patients had received pre- and postoperative
herapy with cephalothin or cephalexin; in case 3,
the patient had been treated with a 5-day course of cephalexin (250 mg, t.i.d.) for an infected hornet bite. In case 1, symptoms of diarrhea and hematochezia with fever were relieved by discontinuation of cephalothin and initiation of i.v. ampicillin and chloramphenicol therapy. In case 2, diarrhea with small amounts of blood developed within a month of hospital discharge. Cholestyramine treatment (2-12 g/day) was required over a period of 9 weeks. In case 3, fever and diarrhea developing within a week of cephalexin treatment responded to cholestyramine treatment (6-12 g daily for 7 days). In case 1, pseudomembranes were not seen sigmoidoscopically, but acute inflammation in the mucosa and inflammatory exudate on the surface were observed histologically. In cases 2 and 3, sigmoidoscopy revealed pseudomembranes, and inflammation was seen histologically. In case 2, the histologically demonstrable inflammation continued after pseudomembranes disappeared sigmoidoscopically. In all cases, stool cultures were negative for pathogens and the diagnosis of PC was confirmed by rectal biopsy. The incidence of cephalosporin-related colitis was shown to be less common than clindamycin colitis but the authors conclude that cephalosporins should be added to the list of antibiotics (chloramphenicol, tetracycline, lincomycin, ampicillin, and clindamycin) associated with PC. They recommend that a biopsy be performed when antibiotic colitis is suspected even when gross inspection reveals only hyperemia and edema. Demonstration of acute inflammation could alert the clinician to the possible development of PC if antibiotic therapy were continued.

8962 PSEUDONEOPLASTIC SIGMOID DIVERTICULITIS: THE VALUE OF I.V. UROGRAPHY IN DIAGNOSIS. (Fre.) Cugnenc, P. H.; Rouanet, J. P.; Loygue, L.; Nouel, O.; Parc, R. (Hopital Saint-Antoine, 184, rue du Faubourg Saint-Antoine, 75571 Paris Cedex 12, France). *J. Radiol. Electrol. Med. Nucl.* 58(12): 801-806; 1977.

In a group of 160 patients treated for sigmoid diverticulitis in the period 1970-1975, the initial diagnosis on the basis of clinical, radiological, and surgical criteria was pseudotumoral sigmoiditis in 63. Further study, particularly x-ray studies, confirmed the diagnosis in 45/63, but the possibility of the presence of cancer was not eliminated preoperatively in the remaining 18. Clinical, radiological, endoscopic, and surgical exploration of these 18 patients is discussed, and a typical case of so-called pseudoneoplastic sigmoiditis is presented. The average age of patients with sigmoiditis is 58 yr, which is close to average age of a series of 258 patients with cancer of the colon, 62 yr. Functional signs do not differ in the two groups, and endoscopy fails to differentiate between cancer and diverticulitis in about 50% of patients. X-ray studies show extensive inflammatory lesions causing changes and thickening in the intestinal muscle wall. Chronic lesions can invade the mesosigmoid, the retrocolic tissue, and neighboring organs, particularly the bladder. Signs of urinary retention, either clinical or observed by i.v. urography, occur in about 20% of patients with sigmoiditis and may be the only symptom in some cases. I.v. urography was performed in 6 of the 18 patients in this series. Typical bladder signs included pseudotumoral changes in the bladder and evidence of external compression, particularly in the area of the left part of the vesical dome, and of retention.

8963 VASCULAR ECTASIAS OF THE RIGHT COLON.

(Eng.) Sprayregen, S.; Boley, S. J. (Montefiore Hosp. and Medical Center, Bronx, NY 10467). *JAMA* 239(10):962-964; 1978.

The use of angiography in the diagnosis of vascular ectasias of the right colon is described, and the results in 25 patients are presented. In a patient with lower intestinal tract bleeding, a nasogastric tube should be passed to exclude gastric or duodenal bleeding. If the findings in this investigation and in coagulation studies, sigmoidoscopy, and colonoscopy are normal, emergency angiography of the superior mesenteric artery, inferior mesenteric artery, and celiac axis should be carried out, in that order. The technique involves inserting a rectal tube before arterial catheterization. The superior mesenteric artery is catheterized, and the colon is then distended with air. For this artery, 50 ml of a combination of 10% diatrizoate sodium and 66% diatrizoate meglumine is injected at 8 to 10 ml/sec, and filming is at the rate of one film per second for 12 sec, followed by one film every other second for 16 sec. The following angiographic criteria are reliable and important for the diagnosis of vascular colonic ectasias: (a) a densely opacified, dilated, tortuous, slowly emptying intramural vein that remains visualized after the other mesenteric veins have emptied; (b) a vascular tuft, which is best identified in the arterial phase; (c) an early-filling vein, which can be visualized within 4-5 sec; and (d) intraluminal extravasation of contrast medium, refering to a localized, amorphous collection that first appears during the arterial phase of the arteriogram and persists throug out the study. A densely opacified, dilated, tortuous, slowly emptying intramural vein was noted in 92% of the 25 patients with ectasias, and a vascular tuft was present in 74%. An early-filling vein, indicating the presence of an advanced lesion with arteriovenous shunting, was definitely present in 61% and suggested in another 16%. On the basis of previous studies, the authors conclude that vascular ectasias of the right colon are acquired, degenerative lesions that are common in the aging population.

8964 MULTIPLE CAVERNOUS HEMANGIOMAS OF THE COLON.

(Ger.) Wagner, H.; Neugebauer, R.; Bultmann, B. (Rontgendiagnostische Abteilung des Departments Radiologie, Steinhovelstrasse 9, 7900, Ulm/Donau, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 128(2):131-134; 1978.

Cavernous hemangioma of the ascending, transverse, and descending colon; the sigmoid; and the rectum was diagnosed in a 26-yr-old man by rectoscopy, double-contrast rectocoloscopy, and arteriography. The patient was hospitalized for recurrent rectal bleeding and abdominal distention. Arteriography demonstrated vascular tumors in the area of the jejunal artery, the left colonic artery, and the superior rectal artery. This rare condition has been described only 53 times in the literature. Subtotal colectomy with cecorectostomy was successful. The excessively frequent defecation observed after surgery was checked by cholestyrami The diagnostic importance of the double-contrast examination of the colon and of selective angiography in the differential diagnosis of this rare condition is stressed.

8965 HISTOCHEMICAL CRITERIA FOR THE DIAGNOSIS OF HIRSCHSPRUNG'S DISEASE IN RECTAL SUCTION BIOPSIES BY ACETYLCHOLINESTERASE ACTIVITY.

(Eng.) Chow, C. W.; Chan, W. C.; Yue, P. C. K. (Royal Children's Hosp., Flemington Rd., Parkville Victoria 3052, Australia). *J. Pediatr. Surg.* 12(675-680; 1977.

Rectal suction biopsies taken from 96 patients wh presented with chronic constipation or intestinal obstruction were examined to determine the histochemical criteria for diagnosis of Hirschsprung's disease (HD) by acetylcholinesterase (ACh) activity. In 37 of the 96 cases, the diagnosis or exclusion of HD was made by searching for ganglion cells in serial paraffin sections, and histochemical patterns were examined retrospectively to determine the features of a positive and a negative reaction. In the 27/37 cases in which HD was excluded histologically, ACh activity showed staining along the luminal bo der and around lymphoid tissue and diffuse staini of the muscularis mucosae and of bundles of cholinergic fibers in the deeper portions of the submucosa; occasionally, some fine discrete cholinergic fibers were also seen in the muscularis mucosae and lamina propria. In the 10/37 cases di-osed as HD, there were two types of positive ction: type A showed coarse discrete choliner- fibers in the muscularis mucosae and the im- iately adjacent submucosa and sometimes in the ina propria, whereas in type B, the lamina pro- a was devoid of or contained only a few discrete ers. The histochemical criterion for a positive ction was therefore chosen as coarse discrete ers in the muscularis mucosae and adjacent sub- osa. In 59 of the 96 remaining cases, the his- hemical reaction was determined first and checked reliability by histological features. In 42/59 cases showing a negative reaction, gan- on cells could be seen without difficulty; in 17/59 cases with a positive reaction, ganglion ls were absent in all but 2. In one of the ter cases, four degenerate ganglion cells were n in the biopsy taken at 5 days of age; how- r, no ganglion cells were seen in a repeat bi- sy at 7 months. In the second case, a few clus- s of well formed ganglion cells were seen in the m specimen; the absence of ganglion cells in the m and 4-cm specimens was, however, consistent h the diagnosis of ultrashort segment HD. It possible that the former case represents an iology for HD that involves destruction of gan- ion cells by viral infection in intra-uterine and ly postnatal life.

56 A SECRETORY EPITHELIUM OF THE SMALL INTESTINE WITH INCREASED SENSITIVITY TO LE ACIDS IN IRRITABLE BOWEL SYNDROME ASSOCIATED TH DIARRHOEA.

(Eng.) Oddsson, E.; Rask-Madsen, ; Krag, E. (Herlev Univ. Hosp., DK-2730 Herlev, mark). *Scand. J. Gastroenterol.* 13(4):409-416; 78.

determine the cause of malabsorption of water d electrolytes in patients with irritable bowel ndrome with associated diarrhea (IBSD), perfusion dies of the ileum and jejunum were performed in patients with IBSD and compared with identical dies in 10 normal subjects. Simultaneous mea- ements were made of the net movements of water d electrolytes; the lumen to plasma and plasma lumen fluxes of Na, K, and Cl; and the trans- al electrical potential difference (PD) in re- nse to perfusion with glycochenodeoxycholic id (GCDC) at concentrations of 0.25, 0.5, 1.0, 5, and 2.5 mM. In normal subjects, solutions taining 1 mM GCDC stimulated ileal absorption <0.05), while further increases of bile acid ncentration reduced fluid absorption and evoked t secretion. Patients with IBSD showed fluid cretion even when no bile acid was present. eir mean water movement was significantly ($p<0.05$) fferent from that of normal volunteers. In- eased absorption occurred at GCDC concentration 0.25 mM; concentrations above this level in- eased secretion. Expressed graphically, the tient curve is seen as a parallel transposition the normal curve to the secretory side and lower concentrations of bile acids, suggesting increased sensitivity of the secretory epithel- m to the stimulus of GCDC in the patients. In- eased plasma to lumen fluxes appeared to be sponsible for the spontaneous secretion of Na and Cl in IBSD. GCDC reduced the lumen to plasma fluxes of Na and Cl equally in both groups. Therefore, the ileal epithelium in IBSD patients responds normally to GCDC, but may be prestimulated by some other biological mechanism involved in intestinal secretion. The jejunal patterns were similar to the ileal. No changes in the transmural PD were demonstrated. The authors foresee therapeutic implications in the conclusions that the small intestinal epithelium in IBSD, besides being prestimulated by some as yet unidentified agent, shows an increased sensitivity to the stimulus of GCDC.

8967 PRIMARY LINITIS PLASTICA OF THE COLON: REPORT OF TWO CASES AND REVIEW OF THE LITERATURE.

(Eng.) Amorn, Y.; Knight, W. A. (St. Mary's Health Center, 6420 Clayton Rd., St. Louis, MO 63117). *Cancer* 41(6):2420-2425; 1978.

Two cases of primary linitus plastica of the colon (scirrhous carcinoma of the signet ring cell type) are reported along with a review of 20 cases in the literature. A 61-yr-old man had a two-month history of bilateral cramping abdominal pain and diarrhea, a 20-pound weight loss, and five to six watery stools/day containing occult blood. Colonoscopy demonstrated a stricture of the sigmoid colon at 40 cm and a 1-cm polyp distal to the stricture. An air contrast barium enema showed a 5-cm constriction in the mid-sigmoid area with overhanging edges at both ends. Sigmoid resection with end-to-end anastomosis of the colon was performed. A 20-yr-old man had a 3-month history of diarrhea, anorexia, a 20-pound weight loss, and loose watery stools numbering 6-12/day and containing gross and occult blood. Rectal examination showed an indurated area 2-3 cm from the anal verge. At operation, a firm constricting lesion of the rectum was removed with the regional lymph nodes. There was no evidence in either case of disease of the stomach, liver metastasis, or ascites. Pathological studies revealed thickening of the intestinal wall by diffuse infiltrating tumor cells of the characteristic signet cell type and diffuse fibrous tissue throughout the lesion. In the second case, fibrous tissue was especially prominent and cells were very undifferentiated. The most common symptoms of primary linitus plastica were changes in bowel habit (75%), pain and cramps (70%), and blood in stool (gross, 50%; occult, 20%). Characteristic clinical features include a younger age of presentation (average age 56 yr versus 60-70 yr for carcinoma of the colon); a low incidence of hepatic, lung, and bone metastasis ($\leq 15\%$ each); and a high incidence of ovarian (60%) and lymph node-adipose-peritoneal (80%) metastases. The mean duration of survival after diagnosis is only 8.3 months.

8968 RECTAL NECROSIS OF ISCHEMIC ORIGIN: "SPONTANEOUS" AND FOLLOWING AORTO-ILIO-FEMORAL ANGIOPLASTY AND LUMBAR SYMPATHECTOMY.

(Fre.) Saegesser, F.; Roenspies, U.; Garcia-Gil, A.;

Boumghar, M. (Service universitaire de chirurgie "A" Chuv, Lausanne, Switzerland). *Chirurgie* 103(10): 907-921; 1977.

Two cases are reported of rectal necrosis attributed to ischemia, and prevention of ischemia of the gastrointestinal tract after infrarenal angioplasty of the iliac aorta is discussed. The first patient, a 62-yr-old man, developed ischemic proctitis with necrosis after an angioplastic operation that involved the aorta and iliac and femoral vessels. However, it is concluded that the ischemia was the result of the low blood flow in pelvic vessels that were obstructed or stenosed. Segmentary resection of the distal part of the sigmoid colon and the upper two-thirds of the rectum was performed on this patient. The surgical specimen showed gangrenous necrosis of the entire gastrointestinal wall with edema and bloody effusion. One year after surgery, rectoscopy showed cyanotic mucosa but no macroscopic ulceration. The second patient, a 68-yr-old man, had necrotic ischemia of the rectal wall as a consequence of repeated episodes of low cardiac output due to paroxysmal tachycardia associated with the Wolff-Parkinson-White syndrome. A recto-sigmoidal resection that included the proximal two-thirds of the rectum was performed. The surgical specimen showed total obliteration of the intestinal mucosa by ulceration and necrosis. Recovery from surgery was satisfactory.

LARGE INTESTINE

Ulcerative Colitis

:4 CLINICAL OBSERVATIONS ON ULCERATIVE
COLITIS. (Eng.) Watanabe, H.; Hiwatashi,
; Yamagata, S. (Tohoku Univ. Sch. Medicine,
ıdai 980, Japan). *Tohoku J. Exp. Med.* 123(3):
7-213; 1977.

: incidence, symptoms, clinical features, compli-
:ions, treatment, and prognosis of ulcerative
.itis were studied in 159 patients. These cases
:urred in a total of 102,519 out-patients
Japan between 1954 and 1975, which is 0.15%
gher than was believed to occur. The age dis-
.bution at the initial examination displayed a
ıodal curve in the 79 male patients, with the
.mary and secondary peaks in the second and
:th decades; there was a unimodal curve in
: 80 female patients, with the peak in the
ırth decade. A unimodal curve with the peak in
: third decade was seen in all patients combined.
the 94 patients investigated for blood type, 42%
e group A, 17% group B, 31% group O, and 10% AB.
precursory symptoms in 109 patients with total
left-sided colitis were mucous blood stools in
and abdominal pain in 11%. In 42 patients with
ctitis, 83% had mucous blood stools, 17% had
rrhea, and 14% had abdominal pain. A tempera-
e above 37.5 C, a >15% weight loss, diarrhea
stools/day), increased ESR, anemia, leukocytosis
,000/mm^3), hypoproteinemia (<6.4 g/100 ml), de-
ased albumin/globulin ratio (<1.03), and hypopotas-
ia (<3.5 mEq/l) occurred in 21 of 75, 34 of 73,
of 91, 66 of 90, 43 of 85, 34 of 85, 33 of 86,
of 82, and 11 of 74 patients with total and left-
ed colitis, resp., and in 0 of 27, 3 of 27, 2
34, 11 of 28, 6 of 24, 6 of 24, 4 of 30, 7 of 24,
0 of 19 patients with proctitis, resp. Proc-
igmoidoscopy in 79 of 95 patients with total and
t-sided colitis in the active stage showed rough
granular mucosa, and erosion was present in 62.
se findings were present in 38 of 43 patients
h proctitis. Cytologic findings in 95 patients
h active total and left-sided colitis included
ge numbers of neutrophils and the presence of
sma cells in 90 and 67, resp.; these features
urred in 39 and 29 cases, resp., among 43
ients with proctitis. Biopsy specimens from all
patients showed goblet cell depletion, crypt abscess, and erosion. Complications in 114 patients with total and left-sided colitis included pseudopolyposis (39), toxic megacolon (3), arthritis (8), stomatitis (3), erythema nodosum (1), and erythema exudativum multiforme (1). Complications in 44 patients with proctitis included pseudopolyposis (6) and arthritis (2). Remission was achieved in 65.5% of the cases followed up. Mortality in these 110 cases was 2.7%. Colectomy was performed in 27.3% of the cases, while ileostomy was carried out in only one case. Among the patients who did not undergo surgery, most were able to return to their occupations.

9025 PRECANCEROUS EPITHELIAL DYSPLASIA IN ULCERATIVE COLITIS: HISTOLOGICAL POSSIBILITY OF EARLY DIAGNOSIS OF COLITIS CARCINOMA. (Ger.) Otto, H. F.; Gebbers, J. O. (Pathologisches Institut der Universitat Hamburg, Martinistrasse 52, D-2000 Hamburg, W. Germany). *Virchows Arch. [Pathol. Anat.]* 377(3):259-276; 1978.

The histology of rectal and colonoscopic biopsy specimens from 20 patients with longstanding colitis (4-22 yr) was studied to determine if precancerous changes are useful for detecting early cancer in colitis. Some patients were monitored by colonoscopy and biopsy for up to 7 yr. A histological study was conducted of rectal and colonoscopic biopsy specimens from 20 patients with colitis of 4- to 20-yr duration. Surgical specimens from a second group of 39 proctocolectomy patients with precancerous epithelial lesions were examined retrospectively; the duration between initial clinical symptoms and proctocolectomy was 3 to 9 yr. Premalignant changes were found in 12 rectal and 14 colonic biopsies from the 20 patients. In the retrospective study, only 3/39 patients were found to have had precancerous lesions. Histologically, the precancerous lesions found among the biopsies could be divided into atypical basal cell proliferation, light-celled epithelial dysplasia, epidermoid metaplasia with atypical cells, adenomatous dysplasia, and intermediate forms. Demonstration of severe epithelial dysplasia led to proctocolectomy in 7 of the 20 patients, with an interval of about 2 yr between discovery of dysplasia and surgery. Two of these patients had a carcinoma; the remaining patients were tumor-free. A progression of dysplasia forms could not be demonstrated in any individual, but epidermal metaplasia and atypical basal cell proliferation appeared relatively soon, after 6 and 8 yr of colitis, while adenomatous and villous dysplasia only appeared after a longer period of colitis. Adenocarcinoma always appeared with adenomatous or villous dysplasia, and never with atypical basal cell proliferation. These forms thus present grounds for proctocolectomy.

9026 ANTIBODIES TO SYNTHETIC POLYRIBONUCLEOTIDES IN SPOUSES OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE. (Eng.) DeHoratius, R. J.; Miller, W. C.; Gaeke, R. F.; Strickland, R. G.; Volpicelli, N. A.; Kirsner, J. B.; *et al.* (Dept. Medicine, Univ. New Mexico, Albuquerque, NM 87131). *Lancet* 1(8074):1116-1119; 1978.

To investigate whether RNA viruses are involved in the etiology of inflammatory bowel diseases, sera of 28 patients with Crohn's disease; 16 patients with ulcerative colitis; normal age-, sex-, and race-matched controls; and the unaffected spouses of all subjects were examined for the presence of antibodies to synthetic polyribonucleotides. Significantly more synthetic single-stranded RNA (poly-rA) was bound by serum from patients (230 ng/ml) and from their spouses (185 ng/ml) than by serum from the controls (75 ng/ml, $p<0.002$) or the spouses of the controls (78 ng/ml, $p<0.01$). Similarly, significantly more synthetic double-stranded RNA (poly-rA-poly-rU) was bound by serum from the patients (501 ng/ml) and by serum from their spouses (468 ng/ml) than by serum from the controls (199 ng/ml, $p<0.002$) or by serum from the spouses of the controls (66 ng/ml, $p<0.02$). Binding of poly-rA-poly-rU was similar in patients with Crohn's disease and ulcerative colitis. Poly-rA binding was lower in the patients with ulcerative colitis but was still significantly higher ($p<0.05$) than in matched controls. Binding activity resided in immunoglobulin fractions and was predominantly of IgM class. A significant correlation was observed between the amount of double-stranded but not single-stranded RNA bound by serum from patients and from their respective spouses ($r=0.4$, $p<0.02$). These findings provide indirect support for the presence of RNA viruses in patients with inflammatory bowel diseases and the transmission of such agents to their close personal contacts.

9027 TEN YEARS EXPERIENCE WITH INTRAVENOUS HYPERALIMENTATION AND INFLAMMATORY BOWEL DISEASE. (Eng.) Mullen, J. L.; Hargrove, W. C.; Dudrick, S. J.; Fitts, W. T., Jr.; Rosato, E. F. (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Ann. Surg.* 187(3):523-529; 1978.

An analysis of parenteral nutritional support provided by i.v. hyperalimentation (IVH) to 74 patients with inflammatory bowel disease (IBD) durin 1967-1976 is presented. The patients, 24 with ulcerative colitis (UC) and 50 with granulomatous disease (GD) of the small bowel, colon, or combine disease of both, underwent 117 courses of IVH. Or admission for treatment, the patients were malnourished with a weight loss of more than 10% in 63 of them. The malnutrition was of the marasmic-kwashiorkor type with a marked depletion of body-cell mass (weight loss, 19 ± 3 pounds; serum albumin level, 2.9 ± 0.13%; serum transferase level 158 ± 13.2 mg%). Indications for parenteral nutritional support included nutritional preparatio for operation (33%), failure of medical treatment (61%), and the poor nutritional status of the patient (48%). Seventy-seven percent of the patien gained weight on IVH, averaging 10 pounds over th course of treatment (about 3.5 weeks). Almost 40 of the patients who had previously failed on medi cal regimen had an IVH-induced remission. Therap before IVH treatment was often of the multiple-drug variety, including steroids, 51%; salicylazo sulfapyridine, 51%; and opiates, 57%. After IVH, the amounts of these medications required were 35 20%, and 26%, resp. No mortality was attributed IVH, and complications arose from IVH in only eig patients. Seventeen of 43 enterocutaneous fistulas found in 25 patients were closed with IVH alone. As only three of these recurred, the over all closure rate with IVH alone was 33%. In the surgical ulcerative colitis patients, a correlati was noted between the occurrence of surgical complications and the absence of preoperative stero treatment. The 10-yr review shows that IVH can ameliorate malnutrition in IBD patients. Combine with complete bowel rest, it can be an effective primary treatment (particularly for GD) or an adjunct to the surgical management of the complications of IBD. Criteria for the use of IVH in IB are given, and it is noted that, since its effica has been documented, nutritional support can be offered to these patients at an earlier stage in the disease.

9028 FILIFORM POLYPOSIS. (Eng.) Zegel, H. G.; Laufer, I. (Hosp. Univ. Pennsylvan 3400 Spruce St., Philadelphia, PA 19104). *Radio ogy* 127(3):615-619; 1978.

The cases of four patients with filiform polypos are presented. This disease was associated with inflammatory bowel disease in three cases, but t fourth patient, a 77-yr-old man, had no prior history of inflammatory disease. The first pati was a 36-yr-old woman who had experienced an epi sode of ulcerative colitis 2 yr previously but h been in almost complete remission prior to follo up examination. At this time, a stricture of th transverse colon was found. A subtotal colectom with ileorectal anastomosis was performed. Path ological examination of the specimen confirmed the presence of a benign stricture and multiple inflammatory polyps, some of which had a long, thin filamentous structure. The second patient was a 20-yr-old woman with granulomatous colitis

had been asymptomatic for 4 yr, but a double
trast enema showed several long, filamentous
ling defects on a background of normal mucosa
the transverse and descending colon. No fur-
r diagnostic or therapeutic procedures were
icated. The third patient, a 33-yr-old man,
an 8-yr history of Crohn's disease involving
small bowel and rectum. He developed epigas-
c pain, dysphagia, and vomiting, and a double
trast gastroduodenal examination showed defor-
y of the antrum and pylorus with some loss of
cular folds in the proximal duodenum. There
extensive involvement of the distal duodenum
proximal jejunum by Crohn's disease. Num-
us, small filamentous filling defects were noted
the body of the stomach. Multiple biopsy
cimens showed that these lesions were composed
irely of normal gastric tissue. Biopsies around
margin of a gastric ulcer adjacent to the
troesophageal junction were compatible with
te gastritis but showed no evidence of granuloma
mation. The last patient presented with rectal
eding, and a filiform polyp of the distal colon
found. Biopsy showed acute and chronic mucosal
lammation, which could indicate either that un-
ognized ulcerative colitis or ischemic colitis
been present. It is important to recognize
iform polyposis as a benign, nonspecific se-
la of prior, severe inflammatory disease.

9038 LIPASE ACTIVITY IN BLOOD FOLLOWING ENDOSCOPIC PANCREATOGRAPHY: DEMONSTRATION OF ITS PANCREATIC ORIGIN AND EXISTENCE OF DUCTAL OR ACINO-VENOUS PATHWAYS IN MAN. (Eng.) Figarella, C.; De Caro, A.; Oi, I.; Sahel, J. (Unite de Recherches de Pathologie Digestive, U 31 Inserm 46, Chemin de la Gaye-13009 Marseille, France). *Scand. J. Gastroenterol.* 13(4):393-399; 1978.

The origin of serum lipolytic activity observed in patients undergoing endoscopic retrograde cholangiopancreatography (ERCP), whether or not followed by nephrography, was investigated. Immediately before and 30 min after cannulation of the Wirsung duct, serum lipase was obtained from 569 patients suspected of pancreatic or biliary disease and who underwent ERCP. The serum lipase properties were compared with those of pancreatic lipase isolated from pancreatic juice obtained by hormonal stimulation of 17 patients before ERCP. Both pancreatic and serum lipase were inhibited by biliary salts above their critical micellar concentrations; the inhibition was reversed by addition of colipase. Studies of serum and pancreatic lipase by chromatography on Sephadex G-100, by electrophoresis, and by double-diffusion immunological assays gave identical results, leading to the conclusion that the serum lipolytic activity in the patients after ERCP was undoubtedly of pancreatic origin. Studies of the patients by post-ERCP nephrography showed an increase in serum lipolytic activity immediately after cannulation of the pancreatic duct and hormonal stimulation and before injection of contrast medium. Activity increased after injection of the dye, leading to pancreatography followed by nephrography, then decreased slowly to a normal value at 40 hr after examination. The presence of pancreatic enzyme activity in serum and the concomitant visualization of the nephron after injection of contrast medium agree with results of previous animal experiments and suggest the presence of acino- or duct-venous pathways in man. In addition to hormonal stimulation, the presence of a tube into the Wirsung duct seems to be necessary to permit an eventual acino- or duct-venous passage. Speculating on the apparent lack of colipase in the serum of certain patients with lipolytic activity and noting that the increased levels of pancreatic enzymes in the ERCP cases are similar to those seen in cases of acute pancreatitis (10-40 times normal), the authors suggest that the estimation of pancreatic enzymes in the blood may be useful in the diagnosis of acute pancreatitis and that the catalytic assay of pancreatic lipase in the blood performed in the presence of an excess of colipase may be a useful test because of its simplicity and rapidity.

9039 BILE ACID METABOLISM IN CYSTIC FIBROSIS. (Eng.) Eklund, A.; Norman, A.; Strandvik, B. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* (Baltimore: University Park Press): 241-246; 1977.

Because cirrhosis and liver damage may occur without the usual liver function tests being abnormal, bile acid metabolism and urinary excretion of bile acids were studied in 15 patients (aged 11 months-18 yr) with cystic fibrosis; all of them had gastrointestinal symptoms and increased fecal fat despite pancreatic enzyme therapy, 14 had pulmonary symptoms, 1 had celiac disease, and 1 was recoverin from severe malnutrition due to anorexia nervosa. Liver function tests were normal in all but two patients who showed moderate increases in one or two parameters; BSP retention and/or i.v. galactose elimination were normal in all patients. Of the ad ministered amount of ^{14}C-cholic acid, 13-77% was excreted during the 4-day sampling period; 11-71% of the dose was excreted in the feces; 1-19% of th excreted amount was found in the urine with the pe centage increasing significantly with age (r=0.780 p<0.001). Total urinary bile acid excretion increased with age (from 1 to 27, μmol/day), most of which was due to other than primary bile acids; bi acid concentration (correlated to body weight and square meter body surface) increased in the same way. Bile acids were excreted as free acids (containing most of the trihydroxy bile acids), glycin or taurine conjugates, or sulfated conjugates (con taining almost all the monohydroxy bile acids). Despite normal liver function tests, the urinary excretion of isotope after ^{14}C-cholic acid administration increased with age in patients with cyst fibrosis. The urinary bile acid pattern in these patients corresponds to that found in healthy chil dren, but the concentration is higher.

9040 SUBCUTANEOUS CYTOSTEATONECROSIS OF PANCREATIC ORIGIN: SURGICAL PROBLEM IN 5 CASES. (Fre.) Mornet, P.; Guivarc'h, M.; Morin, M.; Marquand, J. (Centre medico-chirurgical Foch, 92151 Suresnes, France). *J. Chir. (Paris)* 114(6): 427-442; 1977.

Five patients with subcutaneous cytosteatonecrosis (Weber-Christian syndrome of pancreatic origin) are reported, and the 68 cases in the world literature are reviewed. The pancreatic pathology was pancreatitis in four patients, only one of whom was an alcoholic, and cancer of the pancreas in one. All five patients had subcutaneous nodule and inflammed painful finger or toe and other joi abdominal pain and weight loss were experienced b some patients. Elevated levels of amylase in blo and urine and elevated blood lipase level led to suspicion of pancreatic pathology. Abdominal barium transit x-rays showed enlarged duodenum with or without pancreatic calcification in three of f patients. Laparotomy revealed the presence of ca cer of the pancreas and hepatic metastases in one tient who had no subsequent treatment. Cystoduod stomy and duodenopancreatectomy, resp., were performed on two patients with excellent results. T remaining two patients, one of whom was the alcoh died with widespread cytosteatonecrosis despite c jejunostomy and cholecystostomy in the alcoholic and intensive medical treatment with corticosteroids, antienzymes, and aspiration in the other. It is concluded that recovery is possible if earl

cision of the affected portion of the pancreas or
pass surgery is performed.

)41 RUPTURED PANCREATIC PSEUDOCYSTS: DIAGNO-
SIS BY ENDOSCOPY. REPORT OF 3 CASES.
ng.) Bretholz, A.; Lammli, J.; Corrodi, P.; Knob-
uch, M. (Med. Univ.-Klinik, Ramistrasse 100,
-8091, Zurich, Switzerland). *Endoscopy* 10(1):
-23; 1978.

report of three cases of endoscopically proven
ontaneous perforation of a pancreatic pseudocyst
to the stomach is presented. A 37-yr-old man
th a noncontributory history, a 40-yr-old man
th a history of multiple bulbar and duodenal
cers, and a 35-yr-old alcoholic man with a his-
ry of acute pancreatitis all presented with acute
per gastrointestinal bleeding. The first pa-
ent, who was being treated with anticoagulants
r an acute calf-vein thrombosis, had a clinically
lent bout of acute pancreatitis (suspected be-
use of an elevation of the amylase level and
eated with parenteral nutrition and gastric as-
ration) with pseudocyst formation. Endoscopy
vealed a large circumscribed protrusion in the
sterior wall of the stomach with a hemorrhagic
cosa and giant mucosal folds in the corpus. A
cm-wide opening in the fundus developed, and
osed slightly over 2 months. The patient was
ing well at 1-yr follow-up. The second patient,
o had had caudal pancreatic resection for active
docrine adenomata, had perforation of a pancre-
ic pseudocyst 1 yr later. There was severe dif-
se erosive and hemorrhagic gastritis, perfora-
on of the retrogastric process, and a 4-cm open-
g into a pseudocyst filled with necrotic material.
e patient recovered with conservative treatment.
the third patient, bleeding recurred after 2
eks of conservative management, necessitating
parotomy. An 8-cm pseudocyst in the pancreatic
il and eroding the gastric wall was found. The
udal part of the pancreas and the proximal part
the stomach were resected and an end-to-end
ophago-antrostomy performed.

Pancreatitis

9053 EFFECT OF PROLONGED ADMINISTRATION OF CORTICOSTEROIDS ON EXOCRINE PANCREATIC SECRETION IN MAN. (Fre.) Bourry, J.; Sarles, H. (INSERM U-31, 46, chemin de la Gaye, F 13009 Marseille, France). *Gastroenterol. Clin. Biol.* 2(2): 139-144; 1978.

Because treatment with corticosteroids causes acute pancreatitis in man, exocrine pancreatic secretion was analyzed before and after stimulation with secretin (1 clinical U [CU]/kg) and cholecystokinin-pancreozymin (CCK-PZ, 3 Crick-Harper-Raper U/kg) in 19 patients without pancreatic disease treated with corticosteroids for 46 days to 22 yr. The corticosteroids used in their treatment included betamethasone, triamcinolone, dexamethasone, methylprednisolone, prednisolone, prednisone, hydrocortisone, and tetracosactide. Pancreatic function was compared with that of a control group of 19 sex-, age-, and weight-matched patients without pancreatic disease or steroid treatment. The single sample of pancreatic excretion taken 15 min prior to injection of secretin and CCK-PZ and the two samples taken 15 min and 30 min afterwards were analyzed for lipase, chymotrypsin, phospholipase, bicarbonate, and calcium levels. The absolute concentration of lipase and chymotrypsin and the difference in their concentrations before and after pancreatic stimulation were all significantly ($p<0.05$-0.001) higher in the corticosteroid-treated patients. It is suggested that the hypersecretion of enzymatic proteins in pancreatic fluid of patients on corticosteroids may be the cause of pancreatic lesions.

9054 THE ACTIVITY OF PHOSPHOLIPASE A IN DUODENAL JUICE UNDER PANCREOZYMIN SECRETIN STIMULATION IN CHRONIC PANCREATITIS. (Eng.) Hashihira, S.; Saito, S.; Saeki, M.; Nishii, T.; Takeda, Y.; Mori, R.; *et al.* (Osaka Medical Coll., Takatsuki, Osaka, Japan). *Jpn. Arch. Int. Med.* 24(11): 397-404; 1977.

The cholecystokinin-pancreozymin (CCK-PZ) and secretin tests were carried out in 25 patients with pancreatitis and 18 controls to compare amylase secretion with phospholipase A (PLA) secretion. Eleven patients had calcifying pancreatitis, 5 had definite noncalcifying pancreatitis, and 9 were suspected of having noncalcifying pancreatitis. Controls and patients with pancreatitis showed maximal PLA output 10 min after pancreozymin (1 U/kg body weight, i.v.) stimulation and minimal levels at 40 and 60 min following secretin (1 U/kg body weight, i.v.) stimulation. Stimulated PLA output tended to be lower in the patients with pancreatitis than in the controls, and in the patients with calcifying pancreatitis, this difference was statistically significant ($p<0.05$, 70 min after pancreozymin-secretin stimulation). The amylase output displayed a similar tendency. Although individual deviations were sometimes seen, the total output of both enzymes showed a significant positive correlation ($r=0.837$, $p<0.01$). The PLA/amylase ratios in the patients with calcifying pancreatitis, definite noncalcifying pancreatitis, and suspected noncalcifying pancreatitis, (1.48 ± 0.04, 1.45 ± 0.03, and 1.44 ± 0.03) were significantly higher than those in the controls (1.35 ± 0.02, $p<0.05$). This suggests that PLA maintains its secretory function better than does amylase during pancreatitis.

9055 EARLY OR DELAYED OPERATION IN ACUTE HEMORRHAGIC-NECROTIZING PANCREATITIS? (Eng.) Neher, M.; Mangold, G.; Schonborn, H. (Chirurgische Klinik der Universitat Mainz, W. Germany). *Chir. Gastroenterol.* 11(2):249-252; 1977.

Survival was assessed in patients who underwent early and late operation for necrotizing pancreatitis. Of the 26 patients with acute pancreatitis who underwent early surgery (i.e., after the appearance of necrosis but before the beginning of mortally dangerous complications), 17 had only partial necrosis; 11/17 survived. Of the nine patients who underwent early surgery and had total necrosis, eight survived. Digital removal of necrotic tissue or left-sided resection was possible in the surviving patients. Twenty-three of 32 patients who underwent delayed operation (i.e., after the acute phase) survived. The techniques used were digital removal of sequestric tissue and left-sided resection. The authors conclude that the surgical treatment of total pancreatic necrosis should begin before the onset of lethal complicatio but that operation may be delayed for partial pancreatic necrosis, if there are no initial complications or there is no deterioration in the patient's clinical condition.

9056 ALTERATION OF SURFACTANT CHEMISTRY IN EXPERIMENTAL HEMORRHAGIC PANCREATITIS. (Eng.) Maciver, A. G.; Metcalfe, I. L.; Possmayer, F.; Harding, P. G. R.; Passi, R. B. (Univ. Hosp., 339 Windermere Rd., London, Ontario, N6A 5A5 Canada). *J. Surg. Res.* 23(5):311-314; 1977.

The hypothesis that the direct alveolar damage seen in acute pancreatitis may occur secondary to enzymatic degradation of pulmonary surfactant by pancreatic lecithinase was tested in dogs in which hemorrhagic pancreatitis was experimentally induced by transduodenal low pressure injection of autologous bile (0.5 ml/kg) into the main pancreatic duct. Experimental and sham-operated control animals were ventilated for 12 hr and then sacrificed. Saline lavage of the pulmonary alveoli was conducted, and the collected suspension was centrifuged. The lipid was extracted with chloroform; methanol and the phospholipids were separated and assayed by thin-layer chromatography. The total yield of phospholipid was significantly reduced in the experimental group (1.93 ± 0.23 mg/k

dy weight) in comparison with that in controls
.21 ± 0.24 mg/kg, $p<0.005$). The lysolecithin
action was significantly increased in the exper-
ental versus the control group (5.85 ± 0.32%
rsus 1.31 ± 0.16%, $p<0.001$). The minimum surface
tivity of a pulsating bubble in a suspension of
e extracted lung wash over 5 min was significantly
creased in the experimental dogs (22.4 ± 5.9
nes/cm) in comparison with that in controls (1.7
0.8 dynes/cm, $p<0.01$). These results demonstrate
at the recovery of surfactant is reduced and that
e percentage of lysolecithin is increased in
morrhagic pancreatitis, which supports the stated
pothesis.

57 PANCREATITIS FOLLOWING KIDNEY TRANSPLANTATION. (Ger.) Scholzel, E.; Largiader,
; Uhlschmid, G.; Binswanger, U.; Corrodi, P.;
oblauch, M. (Chirurgische Universitatsklinik A,
rich, Switzerland). *Schweiz. Med. Wochenschr.*
8(5):161-165; 1978.

ncreatitis following kidney transplant presents
serious, often life-threatening complication.
llow-up of 249 recipients of cadaver renal al-
grafts showed that 14 had contracted pancreatitis
week to 7 yr and 4 months following transplanta-
on. Five patients died as a direct result
the disease, while pancreatitis discovered
autopsy was implicated in the death of two
tients. The incidence of pancreatitis was 5.6%,
th a mortality rate of 50%; participation of
ncreatitis in death was 7%. Etiologic factors
this complication included pancreatic damage
used by chronic uremia before the transplant,
eatment with L-asparaginase, and damage from in-
ctions. Pancreatitis following kidney trans-
antation is thus thought to be of multifactorial
igin, with steroid therapy predominant in causing
ncreatic damage.

58 PANCREATITIS FOLLOWING SPINAL CORD INJURY. (Eng.) Carey, M. E.; Nance, F. C.; Kir-
s, H. D.; Young, H. F.; Megison, L. C., Jr.;
ine, D. G. (Louisiana State Univ. Medical Center,
42 Tulane Ave., New Orleans, LA 70112). *J. Neuro-
rg.* 47(6):917-922; 1977.

x cases of pancreatitis following spinal cord in-
ry in otherwise healthy individuals are reported.
ur patients manifested signs and symptoms of
ert pancreatitis having variously, fever, pro-
acted nausea, vomiting, or epigastric tenderness.
o patients died from the effects of grossly or
croscopically confirmed acute hemorrhagic pan-
eatitis. All patients had ileus because of their
rd lesion. None had hyperparathyroidism, amino-
iduria, hyperlipemia, hemochromatosis, or chole-
thiasis, and none was alcoholic. Only one pa-
ent may have sustained pancreatic trauma, and
ly one was hypothermic. The possibility of pene-
ating ulcer was excluded in four cases. None of
e patients had prolonged steroid therapy; one
ceived no steroids and another received only a
single 12-mg injection of dexamethasone. No single, etiologically accepted mechanism already postulated to cause pancreatitis can account for all the cases reported. The authors hypothesize that spinal cord disruption may produce pancreatitis by sympathetic-parasympathetic nervous system imbalance resulting in over-stimulation of the sphincter of Oddi. This may lead to stasis of secretions with absorption of amylase into the systemic circulation, and structural pancreatic damage. Pancreatitis in patients with cord injuries is easily overlooked because abdominal pain is usually absent and fever is usually attributed to more frequently occurring pulmonary or urinary tract infections. Recognition of this complication is important to decrease the morbidity and mortality mortality that follows spinal cord damage.

79 AUTOMATIC ANALYSIS OF BSP KINETICS IN
THE NORMAL INDIVIDUAL AND IN LIVER PA-
ENTS. (Ita.) Mattei, M.; Avanzolini, G.; Gnudi,
; Malaguti, P.; Sciarretta, G.; Ruscelli, C.;
al. (Ospedale Maggiore "C. A. Pizzardi,"
logna, Italy). *Minerva Dietol. Gastroenterol.*
(2):79-83; 1977.

gain greater clinical information from the BSP
imination test, injections of 5 mg/kg of BSP in
5% solution were given to 10 healthy individuals,
with nonhepatic digestive disease, 10 with
eatosis, 10 with cirrhosis, 9 with chronic ac-
ve hepatitis, 6 with granulomatous hepatopathy,
with cancer and cirrhosis, and 3 with metastases.
ood samples were taken at various time periods
nging from 4 to 120 min after the injection. The
tention of BSP after 45 min was 1.9 ± 0.5% in
e control group, 3.9 ± 2% in those with non-
patic digestive disease, 12.5 ± 6.6% in those
th steatosis, 24.6 ± 6.5% in those with cirrhosis,
.8 ± 8% in those with chronic active hepatitis,
5 ± 6.6% in those with granulomatous hepatopathy,
± 6% in those with cancer and cirrhosis, and 18 ±
.3% in those with metastases. A two-compartment
erum and liver) mathematical analysis of the
crease in BSP levels was made and the coeffi-
ents of exchange were determined. It is concluded
at the mathematical model is more discriminating
patients with hepatopathy than with other types
disease.

80 ELECTROMYOGRAPHY IN THE DETECTION OF
PERIPHERAL NEUROPATHY IN CHRONIC LIVER
SEASE. (Ita.) Alvisi, V.; Degli Uberti, E.;
alli, G. (Istituto di Patologia Speciale Medica
Metodologia Clinica, Universita degli Studi di
rrara, Ferrara, Italy). *Minerva Med.* 68(62):
83-4191; 1977.

ectromyographic studies were done on 29 patients
o had had hepatopathy for not less than 3 yr (dia-
tics and alcoholics were excluded). The neuro-
gic examination revealed neuropathy (paresthesia,
poesthesia, and osteotendinous hypo-areflexia)
9/29 patients. Among the 13 with chronic latent
patopathy, 4 showed neuropathy, while among the
with overt chronic hepatopathy, 5 had neuropathy.
e velocity of minimum motor conduction (VC MIN)
the ulnar nerve was significantly slower in
tients with chronic latent hepatopathy with
inical signs of neuropathy (47.7 m/sec, $p<0.05$)
an in healthy controls. In these patients,
th the VC MIN and the velocity of maximum con-
ction (VC MAX) for the external poplitic sciatic
rve were significantly slower (37.75 m/sec and
.875 m/sec, resp., $p<0.05$) than in the controls.
patients with overt chronic hepatopathy without
inical signs of neuropathy, the VC MAX (54.476
sec) and VC MIN (48.585 m/sec) of the ulnar nerve
re significantly lower ($p<0.01$) than in the con-
ols. In these patients the VC MAX (44.904 m/sec),
MIN 37.985 m/sec), and the dispersion (6.78 m/sec)
re all lower ($p<0.001$) than in the controls. In
tients with overt chronic hepatopathy showing
inical signs of neuropathy, the VC MIN (46.20
m/sec) and the VC MAX (53.34 m/sec) were significantly lower in the ulnar nerve ($p<0.01$) and the VC MAX (43.06 m/sec), the VC MIN (33.966 m/sec), and the dispersion (8.8 m/sec) were significantly lower ($p<0.001$) for the external poplitic sciatic nerve. The results confirm that in cases of chronic hepatopathy neuropathy can develop.

9081 SKIN REACTIONS CAUSED BY VITAMIN K IN PATIENTS WITH LIVER DISEASE. (Eng.)
Bullen, A. W.; Miller, J. P.; Cunliffe, W. J.; Losowsky, M. S. (St. James' Hosp., Leeds LS9 7TF, England). *Br. J. Dermatol.* 98(5):561-565; 1978.

Six cases are reported in which patients with chronic liver disease developed cutaneous reactions around the site of injection of oil-soluble vitamin K. The erythematous rash appeared at the injection site 7-16 days after the initiation of vitamin K therapy for a raised prothrombin time. In four patients, the rash spread, either towards the sacrum or more frequently, down to the thigh. Resolution occurred with scaling with 9-22 days. The amount of vitamin K given before the onset of the rash varied between 270 and 440 mg. Five patients subsequently received a water-soluble vitamin K analogue with no adverse affects. In two patients skin tested by the intradermal injection of 0.1 ml of the vitamin K preparation within 1 week of the development of the rash, induration and erythema occurred. This reaction was maximal at 24-72 hr. Pruritus occurred at the site of injection from 24 hr to 15 days after the skin test. There was no significant skin reaction in these two patients when menadiol sodium diphosphate or the different components of the oil-soluble preparation of vitamin K were injected. Similar results were obtained in three other patients tested several months after the development of the initial reaction. Lymphocyte transformation was not stimulated by up to 200 µg/ml of the preparation, nor was leukocyte migration inhibited by 500 µg/ml in the one patient tested. Skin biopsy of the lesion showed a nonspecific perivascular infiltration with chronic inflammatory cells in the dermis. Staining for IgG, IgA, IgM, IgE, and the C_3 component of complement gave negative results. Skin testing was also carried out in 10 other patients with chronic liver disease, none of whom had developed a skin reaction to i.m. vitamin, and in 10 healthy controls. Four patients with liver disease and two healthy volunteers developed a reaction to intradermal vitamin K (0.1 ml). The pathogenesis of this reaction remains uncertain, but the authors suggest that large doses of vitamin K are implicated, and that the reaction may not be immunologically determined.

9082 DOES FATTY LIVER INDUCED BY PARENTERAL NUTRITION DEPEND ON THE AMOUNT OF GLUCOSE SUPPLIED? (Fre.) Messing, B.; Bitoun, A.; Galian, A.; Mary, J. Y.; Goll, A.; Bernier, J. J. (Hopital Saint-Lazare, 107 bis, rue du Faubourg-Saint-Denis, F 75010 Paris, France). *Gastroenterol. Clin. Biol.* 1(12):1015-1025; 1977.

A retrospective study of 15 patients fed parenterally for 7-500 days with high protein (0.20-0.55 g N/kg/24 hr) and variable glucose (40-100 kcal/kg/24 hr) showed 4 patients who definitely developed fatty liver and 5 suspected cases. Criteria for selection of the patients for study were (1) absence of hyperlipemia prior to parenteral feeding (triglycerides ≤1.50 g/l, total cholesterol ≤2.60 g/l), (2) absence of evidence of liver disease, (3) absence of diabetes, (4) precisely defined nutrition, and (5) weekly evaluation of liver function and blood lipids. The nine patients with confirmed or suspected fatty liver received significantly ($p<0.015$) higher levels of glucose (68.89 ± 6.05 kcal/kg/24 hr) than did the other six patients (45.83 ± 3.52 kcal/kg/24 hr). In addition, these nine patients had hypertriglyceridemia (1.60-7.60 g/l) with an average increase in triglycerides of 3.27 ± 0.69 g/l compared with an increase of 0.37 ± 0.07 g/l ($p<0.005$) in the six patients without fatty liver. The presence of fatty liver was determined by biopsy and by measurement of the levels of transaminases and alkaline phosphatase; hepatomegaly developed in five patients and icterus in two. It is concluded that glucose should not be excessive in parenteral nutrition, and when necessary to supply caloric needs, fatty acids should be substituted.

9083 HEPATIC HEMANGIOMAS: PITFALLS IN SCINTIGRAPHIC DETECTION.

(Eng.) Good, L. I.; Alavi, A.; Trotman, B. W.; Oleaga, J. A.; Eymontt, M. J. (Hosp. Univ. Pennsylvania, 3600 Spruce St., Philadelphia, PA 19104). *Gastroenterology* 74(4): 752-758; 1978.

Recent experiences with three patients with angiographically proven hepatic hemangiomas that were not always detected by radionuclide blood flow and blood pool scintigrams of the liver are presented. In the first patient, hepatomegaly associated with a large solitary scintigraphic defect of the liver was present. A rapid-sequence flow study after the i.v. injection of 15 mCi of ^{99m}Tc-pertechnetate revealed no flow to the large defect during the 1 min that images were obtained. Ultrasound examination revealed an inhomogeneous echo pattern in the right half of the liver, which suggested a large solid intrahepatic mass. A liver biopsy produced hepatic bleeding, and at laparotomy an extensive cavernous hemangioma was found. Postoperatively, a hepatic arteriogram revealed a massive cavernous hemangioma involving the entire liver. At a second laparotomy, the right hepatic artery was ligated; 1 yr later, a blood pool image revealed a pattern consistent with a hemangioma. The second patient had hepatomegaly with a scintigraphic space-occupying mass in the right lobe. A rapid-sequence flow study revealed no appreciable uptake of the radionuclide in the defect, and a blood pool image showed a smaller defect in the same location, suggesting vascularity in the periphery of the lesion. Hepatic angiography showed a large hemangioma in the right lobe and many other small ones scattered throughout both lobes. The third patient did not have an enlarged liver, but liver scans revealed a solitary defect in the right lobe. On hepatic blood flow and blood pool scans, this lesion appeared to have less activity than did the surrounding hepatic parenchyma. A hepatic arteriogram revealed a solitary circumscribed hemangioma in the posterior aspect of the right lobe. On the basis of this experience, the authors recommend hepatic angiography for definitive evaluation of the vascularity of solitary defects found on routine liver scans.

9084 LYSOSOMAL DISRUPTION IN THE PATHOGENESIS OF HEPATIC DAMAGE IN PRIMARY AND SECONDARY HAEMOCHROMATOSIS.

(Eng.) Peters, T. J.; Selden, C.; Seymour, C. A. (Royal Postgraduate Medica Sch., London, England). *CIBA Found. Symp.* 51(New Series):317-329; 1977.

Evidence that lysosomes accumulate iron in the liver cells of patients with hemochromatosis and that this accumulation is implicated in the pathogenesis of the tissue damage is reviewed. Morphology of liver, spleen, myocardium, bone marrow cells, and enterocytes from patients with iron overload demonstrated prominent lysosomes, presumed to contain iron compounds. The activities of two lysosomal enzymes, acid phosphatase and *N*-acetyl-β-glucosaminidase, were significantly elevated in liver biopsies from patients with primary or secondary hemochromatosis, which was consistent with the intralysosomal accumulation of iron. Subcellular fractionation by sucrose density gradient centrifugation of liver biopsy specimens from a patient undergoing venesection for hemochromatosis showed that at least 85% of both *N*-acetyl-β-gluco minidase and β-galactosidase activities were present as nonsedimentable enzyme remaining in the sample layer. After venesection, the iron conten was about one-third of that in untreated tissue but was still six times greater than that of control tissue. About half the enzyme activity remained in the sample layer, while the remainder was associated with lysosomes. However, the density distribution of the lysosomes was strikingly abnormal, with an equilibrium density of 1.29 compared with 1.20 in control tissue. These high density lysosomes had a unique enzyme composition containing significant amounts of *N*-acetyl-β-glucosaminidase and β-galactosidase activity but relatively little acid phosphatase and β-glucuron dase activity. Biopsy extracts after further venesection showed normal tissue iron concentrations and normal acid hydrolase distribution. Electron microscopy of tissue before treatment showed distended hemosiderin-containing lysosomes Iron-laden lysosomes have also been observed in iron-overloaded rats. Increased activities of acid hydrolases and enhanced lysosomal fragility in liver homogenates have been demonstrated in pa tients but not in experimental animals.

9085 GENETICALLY DETERMINED IMMUNE HYPERREACTIVITY IN HUMAN LIVER DISEASE.

(E Eddleston, A. L. W. F. (King's Coll. Hosp., Londo SE5, England). *Proc. R. Soc. Med.* 70(8):525-529; 1977.

idence suggesting that there is an inherited mune hyper-reactivity in many patients with chron- active hepatitis (CAH) is reviewed. Family udies have shown that many of the first-degree latives of patients with hepatitis B surface tigen (HBsAg)-negative CAH have raised serum mma-globulin levels in the absence of any clin- al or biochemical signs of liver disease; this compelling evidence against the hypothesis that e hypergamma-globulinemia in these patients is tirely secondary to liver damage. In addition, er 60% of these patients have been found to pos- ss the same histocompatibility antigen, HLA-B8. patients with HLA-B8 and HBsAg-negative CAH, e mean titers of antibodies to rubella, measles, ooth muscle, nuclei, and *Escherichia coli* have en found to be higher than in patients without e histocompatibility antigen; in the case of bella antibodies, the difference is significant. ong relatives of all these patients with chronic patitis, the mean titer of rubella antibodies was und to be significantly higher in the first- gree relatives than in the genetically-unrelated ouses, but these high antibody levels were not lated to the presence of HLA-B8. This is evi- nce against the proposed simple inheritance of immune-response gene linked to HLA-B8, but is nsistent with the inheritance of a more general- ed nonspecific increase in immune responsiveness at is under polygenic control. One author has ggested that a defect in the activity of suppres- r T cells may be of central importance in the rsistence of autoimmune reactions and thus the thogenesis of autoimmune tissue injury. The esent author has postulated that HLA-B8 might be marker for such an abnormality in the control of mune responses and that this defect could be the nk between the many different HLA-B8 associated seases. A suppressor T-cell defect would result a failure to switch off immune responses ade- ately, but only when combined with a powerful itch-on mechanism would it lead to very high tibody levels. The parallelism between this pre- cted behavior and the actual findings in patients th CAH and their relatives is remarkably close.

86 SECONDARY HYPERTRIGLYCERIDAEMIA IN PATIENTS WITH PARENCHYMAL LIVER DISEASE. (Eng.)

ose, G.; Windelband, J.; Weizel, A.; Greten, H. linisches Institut fur Herzinfarktforschung an der dizinischen Universitatsklinik, Bergheimer Strasse , D-69 Heidelberg, W. Germany). *Eur. J. Clin. vest.* 7(6):557-562; 1977.

e role of hepatic triglyceride lipase (H-TGL) and asma lipoprotein lipase (LPL) in liver diseases s studied by selective precipitation of H-TGL with ecific antibodies and subsequent measurement of th activities. The subjects included 50 patients th acute hepatitis, 20 patients with chronic tive or persistent hepatitis, 50 patients with ver cirrhosis, and 47 healthy volunteers. All zyme activities are in units of log μmol x 100 ee fatty acids released 1 ml/hr. The mean H-TGL tivity in the 22 normal men was 38.94 ± 4.54, and at in the 25 normal women was 36.66 ± 5.94. The mean levels in the 26 women with acute hepatitis (30.91 ± 8.64, $p<0.05$), the 24 men with acute hepatitis (31.06 ± 20.0, $p<0.05$), the 14 women with chronic hepatitis (29.90 ± 18.80, $p<0.05$), the 13 women with liver cirrhosis (28.40 ± 19.0, $p<0.01$), and the 37 men with liver cirrhosis (29.0 ± 13.8, $p<0.01$) were significantly lower than the corresponding values in the normal men and women. The mean LPL level in women with acute hepatitis (27.40 ± 18.5) was significantly lower ($p<0.01$) than the LPL levels in normal men or women (34.36 ± 4.44 and 32.27 ± 4.55, resp.), but all other levels were similar to the control levels. The possibility of a circulating inhibitor in the patient's serum was ruled out by mixing enzyme preparations from normal controls with plasma from liver patients. Both H-TGL and LPL were not inhibited with increasing amounts of such serum in the incubation medium. The LPL level did not correlate significantly with any liver function test. There were significant correlations between H-TGL activity and the levels of plasma triglycerides ($r=0.3002$, $p<0.05$), alkaline phosphatase ($r=0.4350$, $p<0.01$), and lecithin-cholesterol-acyltransferase (LCAT, ($r=0.2994$, $p<0.05$) in acute hepatitis; between H-TGL activity and SGPT level ($r=0.4836$, $p<0.05$) and between H-TGL and SGOT level ($r=0.4521$, $p<0.05$) in chronic hepatitis; and between H-TGL activity and serum bilirubin level ($r=0.4463$, $p<0.01$), between H-TGL activity and the normotest ($r=0.5966$, $p<0.01$), and between H-TGL and LCAT activities ($r=0.5965$, $p<0.01$) in liver cirrhosis. Total post-heparin lipolytic activity decreased with the severity of liver dysfunction. With improvement, hypertriglyceridemia disappeared with a concomitant increase in the H-TGL and LPL levels. It is concluded that impaired triglyceride metabolism in liver disease is at least partly caused by diminished plasma hepatic TGL activity.

9087 SONOGRAPHY AND CONVENTIONAL RADIOGRAPHY FOR POSTOPERATIVE LOCAL INFECTIONS IN THE UPPER ABDOMEN. (Ger.)

Vogel, H.; Scherer, K.; Eckert, P.; Vogel-Karl, B. (Radiologische Klinik, Universitatskrankenhaus Hamburg-Eppendorf, 2000 Hamburg 20, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 127(5):433-439; 1977.

Sonographic and conventional radiographic examinations were performed on 24 patients with suspected postoperative abscesses and/or empyemas of the upper abdomen. Total or partial pancreatectomy was performed in 5 cases, Billroth I antireflux plastic surgery and other interventions in the upper digestive tract in 12, surgery on the hepatobiliary system in 5, and combined surgery in 2. Thirty-two abscesses and empyemas were subsequently diagnosed by puncture and reoperation. Sonography demonstrated all 8 liver abscesses, 11/21 abdominal empyemas, and 3 abscesses or empyemas in other positions. Radiography demonstrated 5/8 liver abscesses, 16/21 upper abdominal empyemas, and 1 of the remaining lesions. Sonography demonstrated fluid-filled cavities, while radiography showed especially the presence of extraluminal air. The two methods are consequently complementary. Sonography should be the first diagnostic method used whenever postoperative liver abscess is suspected, while radiography should precede sonography in case of suspected postoperative empyema.

9088 HEPATIC FINDINGS IN JUVENILE CHRONIC POLYARTHRITIS. (Ger.) Rau, R. (Stadtspital Triemli, CH-8063 Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 107(35):1235-1237; 1977.

Hepatic findings in patients with juvenile chronic polyarthritis (JCP) and Chauffard's syndrome (CS) are reviewed. Hepatomegaly was found in 2.9% of patients with JCP as strictly defined, in 48% of the patients with incomplete CS, and in 79% of the patients with complete CS. This hepatomegaly increased during recurrences, and disappeared during remissions. Transient jaundice, elevation of amino transferase levels, and delayed BSP excretion were reported, particularly in patients with complete CS; these findings are indicative of impaired liver function. Liver biopsies have been performed only rarely; they demonstrated nonspecific lymphocyte infiltration of portal fields and, in a few cases, autoimmune hepatitis and even liver cirrhosis with portal hypertension. Plasma cell hepatitis with arthropathy can be easily differentiated from juvenile rheumatoid arthritis: in the former, the synovitis is merely transient and disappears under steroid therapy. As in adults, severe liver dysfunction leads to remission of arthritis. Amyloidosis should be considered in every case of long-lasting hepatomegaly.

9089 IMMUNOGLOBULINS IN SERA OF PATIENTS WITH PORPHYRIA CUTANEA TARDA. (Eng.) Kordac, V.; Fucikova, T. (Charles Univ. Prague, Dept. Clinical Immunology, Unemocnice 2, 12808 Praha 2, Czechoslovakia). *Acta Hepatogastroenterol. (Stuttg.)* 25(1):20-22; 1978.

The serum immunoglobulins were investigated in 67 patients with porphyria cutanea tarda (PCT) and compared with those in 163 healthy controls and 37 age- and sex-matched controls. The typical laboratory findings of PCT were confirmed in these patients (increased BSP retention and SGPT level, positive thymol turbidity reaction). IgG and IgM levels were significantly lower in PCT patients without liver cirrhosis (both those not treated, the S group, and those treated with venepunctures, the V group) than in the controls. The IgG and IgM levels were 150 and 175 IU, resp., in controls, 125 IU ($p<0.05$) and 138 IU ($p<0.01$), resp., in the S group, and 142 IU ($p<0.01$) and 163 IU ($p<0.01$), resp., in the V group. The IgA levels in all patients and the IgG and IgM levels in the untreated PCT patients with cirrhosis were not significantly different from control values. The authors suggest that some PCT patients may have an altered humoral immunity.

9090 ERYTHROPOIETIC PROTOPORPHYRIA: JUVENILE PROTOPORPHYRIN HEPATOPATHY CIRRHOSIS AND DEATH. (Eng.) Cripps, D. J.; Gilbert, L. A.; Goldfarb, S. S. (Univ. Wisconsin Sch. Medicine, 1300 University Ave., Madison, WI 53706). *J. Pediatr.* 91(5):744-748; 1977.

The case of an 11-yr-old boy with erythropoietic protoporphyria complicated by severe hepatic cirrhosis and failure is described. The patient had a 10-yr history of photosensitivity. He presented with jaundice, fever, acute dermatitis, edema, and tiredness. Hepatosplenomegaly, ascites, and periumbilical vein distention were present. The patient subsequently developed a gastric ulcer with perforation, and liver function deteriorated. Episodes of hematemesis, due to esophageal varices, occurred, and the patient died. The terminal eryt rocyte protoporphyrin values were 8,650 to 9,650 μg/dl. Stool protoporphyrin was 1,580 μg/g dry weight, and the estimated level in the liver was 57.5 mg/g wet weight. At autopsy, the liver showe typical features of postnecrotic cirrhosis, was greatly enlarged (1,700 g), and distorted by numerous hyperplastic nodules. Masson trichrome stain indicated dense fibrous scars separating hepatocellular nodules. The hyperplastic nodules contained hepatocytes and Kupffer cells containing clumps of brown pigment. When examined by fluorescence microscopy with a quartz iodine tungsten light, the clumps emitted a persisting red fluorescence, and when examined under polarized light, appeared birefringent with prominent Maltese-cross patterns. Ultrastructural examination showed distinct aggregates of crystalline structures. They were composed of short, straight, or slightly curv barlike structures with tapered ends. Lymph nodes in the region of the porta hepatis and around the head of the pancreas contained abundant doubly refractile pigment similar to that of the liver parenchyma. Although severe liver damage in erythropoietic protoporphyria is rare, patients with this disease should be followed regularly with liver function tests, and a liver biopsy at the time of initial diagnosis may be considered.

9091 FERRITIN IN HUMAN LIVER CELLS OF HOMOZYGOUS BETA-THALASSAEMIA: ULTRASTRUCTURAL OBSERVATIONS. (Eng.) Iancu, T. C.; Neustein, H. (Lady Davis Carmel Hosp., Haifa, Israel). *Br. J. Haematol.* 37(4):527-535; 1977.

Iron overload was studied ultrastructurally in 16 biopsy specimens from 10 patients, of whom 9 had homozygous beta-thalassemia and 1 had delta-beta-thalassemia. A number of round or oval lysosomal structures containing lamellae different from myelin figures were seen in all patients, including those with minimal iron overload. Ferritin molecules were seen either forming arrays in relation with the lamellae, or in paracrystalline arrangement, or with no organized form. There were practically no ferritin molecules in subcellular compartments other than cell sap and lysosomes. The concentration of randomly dispersed ferritin molecules in the cell sap of hepatocytes in the three patients under 13 months of age was noticeably lower than that in older patients; the mean number of ferritin particles in the former patients were 0.7, 0.5, and 0.1 particles/cm^2. In patients over

yr of age and up to 22 yr, the cell sap counts
re 4.1-10.6 particles/cm^2, and the counts were
related to age. Hemosiderin was found only
lysosomes and had various densities. Hemo-
derin-containing lysosomes often contained lipid
oplets and/or myelin figures. Compared to hepa-
cytes, the Kupffer cells had a higher concentra-
on of ferritin in the cell sap, the number rang-
g between 20.8 to 30.6/cm^2 in patients older than
yr. In younger patients, the number of particles
s generally lower, but were variable from cell to
ll. Kupffer cells also showed a large number of
on-containing lysosomes. These observations re-
al that ferritin molecules vary in dimension,
rangement, distribution, and aggregation within
bcellular compartments in prolonged iron over-
ad. The round or oval structures in the lyso-
mes are thought to be early secondary lysosomes.
is study shows that the liver cells have a re-
rkably effective defense mechanism against iron
erload, which consists in the possibility of
eping a constant cell sap ferritin plateau by
ntinuous transport of excessive iron into lyso-
mes.

92 ISOLATED LESIONS OF THE PORTA HEPATIS IN
NONPENETRATING TRAUMA OF THE ABDOMEN:
TERIOGRAPHIC DATA. (Fre.) Malvy, P.; Le Neel,
C.; Leborgne, J.; Bourdon, J.; Mitard, D.
otel-Dieu de Nantes, 44035 Nantes Cedex, France).
irurgie 103(7):507-517; 1977.

ree patients with traumatic injuries to the porta
patis due to auto accidents, all of whom were
bjected to arteriographic study, are discussed.
51-yr-old man entered the hospital with multiple
auma including fractures. He was conscious, and
s blood pressure was normal at time of admission,
t he went into severe shock 3 hr later. At
ergency surgery, hemorrhagic peritonitis due to
dissection of the porta hepatis and a wound of the
patic artery was found; the artery was repaired.
follow-up 1-yr selective opacification of the
patic artery showed good vascularization of the
ver. A 48-yr-old man who entered the hospital
shock underwent exploratory surgery. Hemorrhagic
ritonitis was present. A ruptured spleen was
moved. A tear in the hepatic artery was not re-
irable, and the wounded section of the artery was
cised and the two sections linked. However, the
ver failed to regain normal color after the proce-
re. Arteriography performed several days after
rgery revealed a tear in the common hepatic artery
at had not been observed at surgery. The patient
ccumbed to an infection before further surgery
uld be performed. A 37-yr-old man entered the
spital in shock, which improved after blood trans-
sion. On the 5th day of hospitalization, a pro-
essive icterus appeared, and liver function studies
owed a slight increase in amylase, SGOT, and SGPT
tivities. Arteriography showed no anomalies of
e splenic or hepatic arteries; however, flow in
e gastroduodenal artery was interrupted. Surgery
s performed and bile was observed in the peritoneal
uid. A tear in the gallbladder was found as well
a healed wound of the gastroduodenal artery. A
olecystectomy was performed with a choledoschojejuna
anastomosis. The patient recovered and left the hospital 2 months after the accident. Lesions of the porta hepatis are rare, particularly in the absence of associated hepatic damage.

9093 TOXICOLOGY OF COPPER. (Eng.) Hill, C. H. *In: Advances in Modern Toxicology: Toxicology of Trace Elements.* (New York: John Wiley & Sons): 2:123-127; 1977.

Copper toxicology in humans and animals is reviewed. As this metal is encountered in nature, its toxicity is relatively low except in two special circumstances: humans with Wilson's disease are especially sensitive to copper and sheep can be afflicted with copper toxicosis under practical husbandry practices. Ingested copper is absorbed from the stomach and upper small intestine, passes into the blood where it is probably bound to albumin, and passes to the liver. The liver concentrates the copper first in the cytosol, then in the mitochondria, and finally in the nuclei. It reappears in the plasma in the form of ceruloplasmin. The major excretory pathway is via the bile. In Wilson's disease, the liver, kidneys, brain, and cornea accumulate large amounts of copper. Domestic animals, particularly sheep, are more likely to sustain copper toxicosis than are humans, because of copper-containing salt licks and deliberate copper feeding. Sheep poisoning is characterized by the gradual hepatic accumulation of copper over several weeks or months with no outward symptoms, followed by hemolysis, hemoglobinemia, and hemoglobinuria accompanied by the development of jaundice; these occur coincident with the release of copper from the liver. Calves are less sensitive to copper poisoning and only develop symptoms after ingesting 10-fold more copper than required to poison sheep. Copper toxicosis in swine may be related to an induced deficiency of zinc and iron, since these elements have been shown to prevent the jaundice, elevated aspartate transaminase levels, and anemia seen in pigs fed 750 ppm copper. Rats are apparently insensitive to copper poisoning. It appears that copper toxicosis is not a major problem: in humans, the ingestion of excessive copper salts leads immediately to vomiting, whereas animals have a great capacity to store copper in the liver.

9094 CLINICAL DIAGNOSIS OF HEPATOCELLULAR CARCINOMA. (Eng.) Okuda, K.; Kubo, Y. (Chiba Univ. Sch. Medicine, Chiba, 280, Japan). *Kurume Med. J.* 24(Suppl.):S81-S112; 1977.

Clinical features significant for the diagnosis of hepatocellular carcinoma (HCC) and the value of alpha-fetoprotein (AFP) determination and of celiac angiography in diagnosing this disease are presented. Abdominal fullness and distention were early symptoms in 44% of 134 patients with HCC, and abdominal pain occurred in 41.8%. Other symptoms were similar to those in liver cirrhosis. In one patient, a firm mass was felt in the right upper quadrant beside a normal liver edge; at autopsy, the lobe was found to be completely replaced by tumor. In other patients, localization of the tumor is difficult because of displacement of other organs, such as the spleen. Laboratory studies that are important in the diagnosis include alkaline phosphatase, SGOT, and SGPT levels; the SGOT/SGPT ratio; and LDH and AFP levels. The SGOT/SGPT ratio increases gradually during the advancement from chronic liver disease to cirrhosis and from cirrhosis to HCC; the ratio increases sharply during the weeks before death. The authors' own experience as well as the results of previous studies suggest that the AFP level is not always a reliable indicator of HCC. Liver sciniscan is regarded as one of the most reliable diagnostic tools in liver cancer. However, HCC arising in a cirrhotic liver is not readily detected by this method alone. The use of ^{99}Tc-labeled colloid is superior to that of ^{198}Au-colloid in this situation, and the right lateral, posterior, left lateral, and anterior positions should all be used. HCC can sometimes be differentiated from metastatic carcinoma because the parenchyma surrounding the tumor in HCC has low activity, and the defect is not very discrete. Celiac and hepatic angiography often disclose small lesions that have escaped detection by scanning; the former techniques also provide information on the gross form of the tumor. One of the most characteristic angiographic findings in HCC is the presence of arterio-portal shunts. The smallest lesion detected by angiography in the authors' experience was 4 x 4 cm. The authors suggest that three other types of HCC should be recognized (cirrhotic, cholestatic, and hepatitis) aside from the five previously presented in the literature (frank, occult, febrile, acute abdominal, and metastatic).

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

6 CHANGES OF SERUM GONADOTROPIN CONCENTRATIONS IN PREMATURE BABIES SUBMITTED TO OTOTHERAPY. (Eng.) Lemaitre, B.; Toubas, P. L.; llot, M.; Dreux, C.; Relier, J. P. (Hopital St.- is, rue de la Grange-aux-Belles, F-75010, Paris, nce). *Biol. Neonate* 32(3/4):113-118; 1977.

determine whether phototherapy affects plasma adotropin levels, follicle stimulating hormone H) and luteinizing hormone (LH) levels were ermined in eight premature infants who were ated for 2-8 days for hyperbilirubinemia and pared with those in six premature untreated in- ts without jaundice. In the four girls sub- ted to phototherapy, there were significant in- ases in plasma FSH ($p<0.001$) and LH ($p<0.01$) levels during the 3rd and 4th weeks after birth compared with levels in the 1st and 2nd weeks. FSH and LH levels also increased significantly during the 3rd and 4th weeks after birth in the treated newborn girls compared with the levels in controls (FSH $p<0.02$, LH $p<0.05$). In boys who underwent phototherapy, only the LH levels increased during the 3rd and 4th weeks. In both sexes, the rise in gonadotropin levels appeared between 8 and 10 days after the end of phototherapy. No significant changes in gonadotropin levels were observed in any of the controls. Constant phototherapy and/or the sudden stopping of the treatment in the jaundiced premature female newborn is responsible for a marked and transient elevation of gonadotropin.

Nonviral Hepatitis and Hepatic Injury

LIVER AND BILIARY TRACT

17 METHOXYFLURANE HEPATITIS. (Eng.) Min, K. W.; Cain, G. D.; Sabel, J. S.; Gyorkey, F. (Veterans Admin. Hosp., Houston, TX 77211). *South. Med. J.* 70(11):1363-1364; 1977.

A case of fulminant hepatitis due to repeated sniffing of methoxyflurane as a euphoriant is presented. The patient, a 42-yr-old man, presented with nausea, vomiting, icterus, pyrexia, lethargy, and vague, intermittent midabdominal pain. He had a history of heavy alcohol use but had consumed no alcohol for the last 3 yr. He admitted sniffing methoxyflurane for the last 2 months. The patient died in hepatic failure due to submassive hepatic necrosis 3 weeks after hospitalization. Fluorinated anesthetics should be considered as a causative agent in cases of fulminant hepatitis, especially in patients who have easy access to such drugs.

9118 POLYURIC RENAL FAILURE AND HEPATITIS ASSOCIATED WITH METHOXYFLURANE ANESTHESIA. (Eng.) Kalkay, N. M. (Brooklyn-Cumberland Medical Center, Brooklyn, NY). *N.Y. State J. Med.* 77(14):2265-2269; 1977.

A case is presented in which both of the toxic effects of methoxyflurane (hepato- and nephrotoxicity) occurred concurrently, and it is compared with similar cases from the literature. A 62-yr-old man underwent two episodes of retinal surgery 4 weeks apart in which methoxyflurane anesthesia was used. Renal injury manifested immediately: on the day of the second surgery, the patient developed a fever of 100.4 F that lasted 3 days, complained of weakness, dizziness, and excessive thirst, and was noted to have dehydration and orthostatic hypotension. Acute polyuric renal failure lasted 31 days. Hepatic injury began 12 days after the second surgery, manifested by low-grade fever, enlarged and tender liver, elevated transaminase level, and prolonged prothrombin time; it persisted 16 days. The hospital course was complicated by pericarditis, severe hypocalcemia, fluid and electrolytes imbalance, tachyarrhythmia, hypoalbuminemia, hypoprothrombinemia, and anemia. Peritoneal dialysis for azotemia and pericardial involvement was required intermittently for 2 weeks, and liver biopsy could not be done. Prior renal or hepatic disease, other toxic medications, blood transfusion, and shock were ruled out etiologically, and viral hepatitis appeared unlikely. Only four other proved cases of this type with sufficient data are known in the literature. Two different pathogenetic mechanisms appear to be at work. The nature of the renal disease seems to be predominantly tubular, perhaps induced by the direct toxic effects of fluoride. The injury is transient, dose-related, can be produced in experimental animals, and is not induced by halothane. The hepatic injury appears to be induced by an immunologic hypersensitivity reaction, has an unpredictable outcome with a very high mortality rate (perhaps 58%), cannot be produced in experimental animals, and is induced by halothane. Even the safest anesthetic agents are not free of severe side-effects.

9119 HEPATITIS DUE TO PERHEXILINE MALEATE: DEVELOPMENT OF CIRRHOSIS AFTER INTERRUPTION OF DRUG IN TWO CASES. (Fre.) Beaugrand, M.; Chousterman, M.; Callard, P.; Camilleri, J. P.; Petite, J. P.; Ferrier, J. P. (Hopital Jean-Verdier, avenue du 14-Juillet, F 93140 Boudy, France). *Gastroenterol. Clin. Biol.* 1(10):745-750; 1977.

Two cases are reported of liver damage in patients who were chronic users of the drug perhexiline maleate (Pexid). A 66-yr-old man had taken Pexid (200 mg/day for 23 months) to relieve pain associated with a myocardial infarction. He was hospitalized for vomiting and weight loss; his liver was hard and enlarged; and liver function studies and other laboratory tests showed abnormal liver function. Histological examination of the liver revealed sclerosis, inflammatory cell infiltration, and Mallory bodies in specimens of the centrilobular portion. Pexid was discontinued, and the patient was discharged from the hospital without signs of improvement in liver function tests. One month later he was rehospitalized with edema of the lower limbs, icterus, and hepatic encephalopathy, and he died within 2 weeks. A 53-yr-old man used Pexid (300 mg/day for 9 months) together with two other drugs for anginal pain. He was hospitalized for hepatomegaly and weight loss; liver function studies showed elevation of SGOT and SGPT levels and prolonged BSP retention. Mallory bodies and fatty degeneration were observed on microscopic examination of liver biopsies. Pexid was discontinued, and the patient was treated with prednisone. Liver function returned to normal, and histological examination revealed reduced inflammation, micronodular cirrhosis, but no Mallory bodies or hepatocytic lesions 6 months later. Both cases mimicked alcoholic hepatitis initially. The first patient had no history of alcohol consumption, whereas the second consumed no more than half a liter per day.

9120 TOXIC HEPATOSIS DUE TO SALICYLATES IN CHILDREN. (Ger.) Hinkel, G. K.; Korth, G.; Lorenz, K. (Kinderklinik, Medizinische Akademie "Carl Gustav Carus," Fetscherstr. 74, DDR-8019 Dresden, E. Germany). *Dtsch. Gesundheitswes.* 32(35) 1642-1644; 1977.

Three children treated with high doses of the salicylate Micristin (104-150 mg/kg/day) developed toxic hepatosis, which was also confirmed bioptically in one case. The clinical symptoms were mild, but the serum transaminase level was increased considerably in all cases. After normalization of the serum transaminase level, the Micristin therapy was continued at reduced dose (65 mg/kg/day) in one patient without any sign of intolerance. The findings indicate that toxic hepatosis due to high doses of salicylates occurs more frequently than has been assumed before and that the salicylate dose should be limited to 70 mg/kg/day. The serum transaminase level should be controlled regularly during salicylate therapy. Following the resolution of salicylate hepatitis, the salicylate therapy may be resumed after an interval but at a reduced dosage.

CHRONIC HEPATIC INFLAMMATION AND FIBROSIS
DUE TO LOW DOSES OF PARACETAMOL. (Eng.)
owsky, H. L.; Mudge, G. H.; McMurtry, R. J.
erans Admin. Center, White River Junction, VT
01). *Lancet* 1(8072):1016-1018; 1978.

case of a patient in whom liver injury developed
r chronic ingestion of paracetamol in thera-
ic doses is presented. Chronic hepatic necrosis
loped in a 53-yr-old man who had been taking 4
paracetamol daily for about 1 yr (cumulative
1,700 g). Liver biopsy done 23 days after the
was stopped showed prominent diffuse central
osis and portal changes. Repeat biopsy 5
hs later showed chronic active hepatitis. This
pted anti-inflammatory treatment, with subse-
t improvement in liver histology. Liver con-
rations of reduced glutathione and paracetamol
bolism were assessed 1-1.5 yr after the drug
stopped and were normal; the basis for this
ent's drug sensitivity is thus unclear. In
patients, chronic ingestion of therapeutic
s of paracetamol may produce hepatic necrosis
hepatitis that persist long after the drug has
discontinued.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

5 DIFFERENCES IN THE BIOCHEMICAL COURSE OF
HBsAg-NEGATIVE AND HBsAg-POSITIVE HEPATITIS
IS. (Ger.) Strohm, W. D.; Hossenfelder, E.;
lle, W. (Zentrum der Inneren Medizin, Universitat
odor-Stern-Kai 7, D-6000 Frankfurt/Main 70, W.
many). *Z. Gastroenterol.* 16(1):13-23; 1978.

omparison of 73 hepatitis B surface antigen
sAg)-negative patients with 94 HBsAg-positive
ients, all of whom had been free of other dis-
es that could influence the course of hepatitis
or to contracting the disease, was carried out
determine whether the course of the disease
fered in these two groups. SGOT, SGPT, and
irubin levels were higher in HBsAg-positive
ients than in HBsAg-negative patients, and these
els remained higher for a longer time in the
mer group. During the acute stage, 56% of HBsAg-
itive patients had an initial increase in trans-
nase activity, generally with an increase in
de Ritis quotient (SGOT:SGPT), and 15% of the
ients reached a transaminase activity plateau;
y 22% of the HBsAg-positive patients had a
course similar to that of the HBsAg-negative patients. The median duration of the initial transaminase plateau in patients with hepatitis B was 17.9 ± 7.2 days; the duration of HBsAg-positive hepatitis was longer than that of HBsAg-negative hepatitis by more than 10 days. However, the duration of the disease in HBsAg-negative patients was appreciably longer in patients with transaminase recidivism with an increase in bilirubin. In HBsAg-negative patients, SGOT and SGPT values began to decrease immediately following the development of icterus. Laboratory determinations in the first days after the development of icterus were essentially the same in both types. The different biochemical behavior of HBsAg-negative and HBsAg-positive hepatitis may be due to differing immumological reactions of the liver.

9126 HISTOCHEMICAL DEMONSTRATION OF HBsAg IN LIVER BIOPSIES WITH ORCEIN STAINING.

(Ita.) Esposito, R.; Pollavini, G.; Randone, G.; De Lalla, F. (Istituto di Malattie Infettive dell'Universita di Milano, Milano, Italy). *Boll. Ist. Sieroter. Milan* 56(4):316-320; 1977.

The histochemical detection of hepatitis B surface antigen (HBsAg) was demonstrated using orcein stain. Liver biopsies were obtained from 30 HBsAg-seronegative and 33 HBsAg-seropositive individuals (5 were normal and 58 had liver diseases). The tissues were stained according to the modifications of Deodhar. In none of the HBsAg seronegative cases was positive staining obtained with orcein. Of the 33 HBsAg seropositive cases, 18 had hepatocytes whose cytoplasm was stained red-brown: 4/7 from patients with chronic persistent hepatitis, 5/9 from patients with chronic aggressive hepatitis, 6/11 from patients with chronic aggressive hepatitis with cirrhosis, and 3/6 from HBsAg-positive individuals without identifiable liver disease.

9127 SCANNING ELECTRON MICROSCOPY OF THE BILE DUCTULE. (Eng.) Itoshima, T.; Yoshino, K.; Yamamoto, K.; Ohta, W.; Kubota, M.; Ukida, M.; *et al.* (Okayama Univ. Medical Sch., Okayama, 700, Japan). *Gastroenterol. Jpn.* 12(6):476-482; 1977.

Scanning electron microscopy was used to study the bile ductule in a liver needle biopsy specimen from a 29-yr-old man in the convalescent stage of acute hepatitis, the onset of which had occurred 6 months earlier. The sinusoids, Disse spaces, portal triad vessels, tissue spaces, and bile ductule, which were all cleaned by puncture perfusion, were clearly demonstrated. The air crackings tended to occur between the cells and disclosed the intercellular surfaces. The ductule, portal triad, and portal vein branch were 13, 120, and 50 μm in outer diameter, resp. The ductule had sinusoids at the lobule side and tissue spaces and a 7-μm capillary at the portal side. The antiluminal border of the ductule was rather smooth and devoid of microvilli. The ductular lumen was surrounded by two ductular cells (each 18 μm in length), was 1.6-2.7 μm in diameter, and was ampullary dilated (2.7 μm in diameter) at the canalicular side. The canalicular-ductular junction was not evident. Intracytoplasmic diverticula with 0.9-μm diameter orifices were present in the lumen. Microvilli (0.4-0.6 μm long and 0.1 μm thick) were present on the luminal surface of the ductular cell (about 1,500/cell), being denser at the marginal flap and in the diverticula. A single cilium (0.15 μm wide at the base, 0.10 μm wide at the trunk, and 7-15 μm long) arose from a recess at the canalicular side of the ductular cell, and the free end was on the bile duct side. The distance from the luminal to the antiluminal side of the intercellular surface of the ductular cell was 5-6 μm. The outer area of the intercellular surface was undulated but without interdigitation. Occasionally, a cell with thin processes was intercalated between the ductular cells at the edge of the basal portion. The ductular cell surfaces corresponding to the intercalated cell were smoothly depressed and formed a canal 3 μm in diameter parallel to the long axis of the ductule.

9128 CHANGES IN AMINOPHENAZONE METABOLISM IN CHILDREN WITH ACUTE HEPATITIS. (Ger.) Windorfer, A., Jr.; Muller, G.; Stehr, C. (Kinderklinik und Poliklinik, Technische Universitat, Kolner Platz 1, 8000 Munich 40, W. Germany). *Dtsch. Med. Wochenschr.* 102(41):1460-1464; 1977.

The serum concentrations of aminophenazone (AP) were measured in 23 3- to 13-yr-old children with acute viral hepatitis and in 23 age-matched controls with normal livers following the administration of single doses of AP (8-22 mg/kg p.o.), as well as in 5 healthy young adults who received 8-17 mg/kg p.o. of AP. The control children received AP for acute attacks of fever. The serum half-life of AP was 2.85 ± 0.89 hr in the adult controls, 2.79 ± 0.53 hr in the control children, and 6.71 ± 3.34 hr in the children with hepatitis; the difference between the patients and controls was statistically significant ($p<0.1$). The serum AP concentration was highest 2 hr after administration, being somewhat higher in the control children than in the patients with hepatitis, but the difference was not significant due to the wide scatter of the data. The serum half-life of AP increased with increasing SGPT level ($r=0.9$) in the patients, but there was no correlation between the half-life and the dose in either control group. The maximum serum concentration of AP correlated with the dose in the control children ($r=0.84$), but only a weak correlation was seen in the patients ($r=0.38$). The findings indicate the interference of hepatopathy with AP metabolism.

9129 CLINICAL SIGNIFICANCE OF e-ANTIGEN/ANTI-e, WITH SPECIAL REFERENCE TO HBc-ANTIGEN IN THE LIVER. (Eng.) Furuta, S.; Kiyosawa, K.; Nagata, A.; Koike, Y.; Sahara, T.; Furukawa, K.; *et al.* (Dept. Internal Medicine, Shinshu Univ., Matsumoto, 3-1-1, Nagano-prefecture, 390 Japan). *Gastroenterol. Jpn.* 12(6):460-465; 1977.

The prevalence of hepatitis B e antigen (HBeAg), antibody to HBeAg (anti-HBe), and HB core antigen (HBcAg) was evaluated in 34 asymptomatic HB surface Ag (HBsAg) carriers, 8 patients with acute hepatitis, 16 with chronic persistent hepatitis, 36 with chronic active hepatitis, 35 with cirrhosis, and 23 with hepatoma, all of whom were HBsAg-positive. The frequency of HBeAg in these patient groups was 38.2, 25.0, 12.5, 33.3, 5.7, and 0%, resp., and of anti-HBe was 23.6, 50.0, 56.2, 61.1, 80.0, and 78.3%, resp. Among 22 asymptomatic HBsAg carriers, HBcAg was detected in the liver of 4/8 with HBeAg in the serum, 2/9 with anti-HBe in the serum, and 2/5 with neither HBeAg nor anti-HBe in the serum. Among 48 patients with chronic liver diseases, HBcAg was detected in the liver of 4/5 with HBeAg in the serum, 1/5 with anti-HBe in the serum, and 23/38 with neither HBeAg nor anti-HBe in the serum. The serum titer of antibody to HBcAg (anti-HBc) was lower in sera positive for anti-HBe than in sera positive for HBeAg ($p<0.05$), indicating that there may be a decreased level of HB virus replication in patients with anti-HBe. The results emphasize that the investigation of HBeAg and anti-HBe is mandatory for the evaluation of the prognosis of asymptomatic HBsAg carriers and of patients with chronic hepatitis.

9130 BEHAVIOR AND CLINICAL SIGNIFICANCE OF THE eAg/anti-e SYSTEM IN HBsAg CARRIERS.

(Ita.) Pastore, G.; Dentico, P.; Fera, G.; Angarano, G.; Schiraldi, O. (Istituto di Malattie Infettive dell'Universita di Bari, Bari, Italy). *Boll. Ist. Sieroter. Milan.* 56(4):333-338; 1977.

The relationship between hepatitis B e antigen (HBeAg), antibody to HBeAg (anti-HBe), and various forms of liver pathology caused by HB virus (HBV) was studied. Radioimmunoassay and radial immunodiffusion were used to determine HB surface Ag (HBsAg), antibody to HBsAg (anti-HBs), HBeAg, and anti-HBe levels in sera from 315 patients (154 with acute hepatitis, 44 HBsAg-positive asymptomatic subjects, and 117 with chronic hepatitis) drawn weekly during the period of recovery and at less frequent intervals during outpatient follow-up. For those with acute hepatitis, 31/82 who were cured had HBeAg in their sera during the acute phase, 8/82 had anti-HBe in their sera at this time, and all were positive for HBsAg. Six months later, none were positive for HBsAg, 50 had anti-HBs, 2 had HBeAg in their sera, and 25 had anti-HBe antibodies. Of the patients with protracted cases of acute hepatitis, 20/20 had HBsAg, 13/20 had HBeAg, and none had anti-HBe or anti-HBs in their sera during the acute phase. Six months later, 12/20 still had HBsAg, 2/20 had anti-HBs, 8/20 had HBeAg, and none had anti-HBe antibodies. Of the 52 HBsAg-negative patients with acute hepatitis, none were positive for HBeAg or anti-HBe. Of the 117 patients with chronic hepatitis, 28 had neither HBsAg, anti-HBs, HBeAg, nor anti-HBe. Of the 30/117 with chronic persistent hepatitis, 19/30 were HBsAg-positive (10/19 also had HBeAg, and 6/19 also had anti-HBe); 4/30 were anti-HBs-positive (2/4 also had HBeAg, and 1/4 also had anti-HBe). In the 30/117 with chronic aggressive hepatitis type A, 20/30 were HBsAg-positive (17/20 also had HBeAg, and 2/20 also had anti-HBe); 6/30 were anti-HBs-positive (3/6 also had HBeAg, and none had anti-HBe). Of the 9/117 with chronic aggressive hepatitis type B, 7/9 were HBsAg-positive (all also had HBeAg, and none had anti-HBe); 1/9 had anti-HBs and HBeAg but not anti-HBe. Of the 48/117 with cirrhosis, 22/48 were HBsAg-positive (9/22 also had HBeAg, and 1/22 also had anti-HBe); 10/48 were anti-HBs-positive (2/10 also had HBeAg but none had anti-HBe). Among the 44 HBsAg-positive but asymptomatic patients, only one, who was diagnosed as having chronic aggressive hepatitis, was HBeAg-positive, but 24 (17 with a history of acute hepatitis) had anti-HBe. The results confirm an association between HBV infection and the presence of HBeAg and anti-HBe in the serum.

9131 PRESENCE OF SERUM CREATINE KINASE ISOENZYMES IN LIVER FAILURE WITH CEREBRAL INVOLVEMENT.

(Eng.) Lemberg, A.; Werber, D. H.; Gilardoni, A.; Magrino, H. J. (Sch. Pharmacy and Biochemistry, Buenos Aires Univ., Buenos Aires, Argentina). *Clin. Chim. Acta* 80(2):385-390; 1977.

The presence of creatine kinase of the type that is derived from brain cells (BB-CK) in patients with severe encephalopathy and coma is reported. Twelve patients with clinical and biochemical evidence of hepatic failure, one diabetic with hyperglycemia and acidosis, and one with meningococcus purulent meningitis were studied. BB-CK was detected in the sera of all four patients with liver coma due to acute viral hepatitis. BB-CK occurred in three of four patients with cirrhosis and coma but in neither of two patients with chronic active hepatitis and coma. BB-CK was not detected in the sera of any of the remaining patients, all of whom also had severe encephalopathy. Only one patient with acute hepatitis survived, and in this patient the BB-CK disappeared. The enzyme was absent before the onset of encephalopathy in one patient with cirrhosis, but appeared when her condition deteriorated to grade IV coma. The concentrations of the enzyme ranged from 45 to 306 U/l in the patients with acute hepatitis and from 11 to 71 U/l in the patients with chronic liver disease. It seems clear that patients in this study can be divided into three groups: those with acute viral hepatitis, who show high BB-CK content in the serum; those with cirrhosis and chronic active hepatitis, who had either low serum BB-CK levels or none; and those with secondary liver involvement or with no liver involvement but with a severe general condition, in whom no BB-CK is found. Measuring CK isoenzymes in patients with severe liver pathology may help to measure the severity of the disease state.

9132 MODIFICATIONS OF FACTOR VIII RELATED ANTIGEN IN HEMOPHILIACS WITH ACUTE HEPATITIS AND SUB-CLINICAL LIVER DISEASE.

(Eng.) Sultan, Y.; Maisonneuve, P.; Simeon, J.; Intrator, L. (Hopital Saint-Louis 2, Place du Dr. A. Fournier 75475, Paris Cedex 10, France). *Scand. J. Haematol.* (Suppl. 30):16-26; 1977.

Modifications in factor VIII-related antigen (FFRA) were investigated in three patients with hemophilia during the course of post-transfusion hepatitis. The patients were among 36 multitransfused hemophiliacs in whom the mean FFRA level was 148.5% of normal. The level in the 10 hemophiliacs with a normal SGPT level was 112.4% of normal, while that in the 26 hemophiliacs with elevated SGPT levels was 163.2% of the normal level. In the first patient, the FFRA level was 300% of normal 4 days after the onset of jaundice and reached 620% on the 18th day. At that time the bilirubin level was 14.0 mg/100 ml, and the SGPT level was 165 U. The ristocetin cofactor was 280% (less than half the FFRA level). By the 32nd day, the SGPT and bilirubin levels were normal, and the FFRA level was near the normal range, although hepatitis B surface antigenemia persisted. Two-dimensional immunoelectrophoresis of the plasma on the 18th day showed abnormal results. FFRA appeared to be composed of two populations of FFRA molecules with different electrophoretic mobilities; this finding was confirmed by filtration of the cryoprecipitate on Sepharose 4B. The ability of the eluted protein to induce ristocetin aggregation in a washed platelet system was significantly reduced compared with the concentration of antigenic material. The FFRA level at the onset of disease in the second patient was 240% without modification of the procoagulant activity. The clinical symptoms rapidly resolved, and the liver function tests returned to normal. The FFRA gradually normalized. Immunodiffusion of FFRA during the acute phase showed a normal pattern. The third patient had a prolonged course of anicteric hepatitis. The FFRA was 180% during the second month, and this reached 210% after 8 months, during which time the transaminase level was consistently high. The ristocetin cofactor never increased during the course of the disease. Column chromatography of the patient's cryoprecipitate on Sepharose 4B showed the same abnormal elution pattern for FFRA and ristocetin cofactor seen in the first patient. These studies show that FFRA levels parallel the course of acute hepatitis and SGPT levels.

9133 RAPID TURNOVER SERUM PROTEINS IN FULMINANT HEPATITIS.

(Eng.) Kobayashi, K.; Kameda, S.; Sugimoto, T.; Suzuki, K.; Nishimura, K.; Kato, Y.; *et al.* (Kanazawa Univ. Hosp., 13-1, Takaramachi, Kanazawa, Ishikawa, 920 Japan). *Gastroenterol. Jpn.* 12(6):455-459; 1977.

To find reliable indices for the early diagnosis of fatal cases of viral hepatitis, the prealbumin and α_2-heat stable(HS)-glycoprotein levels were measured by immunodiffusion and the Normotest was carried out using sera from 78 patients with biopsy- or necropsy-verified acute viral hepatitis. The patients were divided into three groups according to clinical and histological features: group A, 23 cases of subacute fulminant hepatitis with submassive necrosis and serious signs (e.g., mental disturbance, edema, ascites); group B, 15 cases with zonal or submassive necrosis without serious signs; and group C, 40 cases with spotty necrosis. Fourteen group A patient died. All tests were done before the appearance of hepatic coma or gastrointestinal bleeding. No significant differences were found in the prealbumin (half-life 1-2 days) level between fatal and surviving patients. The α_2-HS-glycoprotein (half-life 4-6 days) level was significantly lower in the fatal group A cases (21.9 ± 7.4 mg/dl) than in the surviving group A cases (37.4 ± 6.9 mg/dl, $p<0.05$); moreover, there was a significant ($p<0.05$) difference between group A overall (27.5 ± 7.4 mg/dl) and group B (60.9 ± 13.9 mg/dl) and an increased value among 30% of group C with respect to the α_2-HS-glycoprotein level. The Normotest showed significantly ($p<0.05$) lower values among fatal group A cases (10.7 ± 4.3%) compared with surviving group A cases (45.3 ± 19.6%) and among group A cases overall compared with group B cases ($p<0.05$). There was a significant correlation between the levels of α_2-HS-glycoprotein and the values of the Normotest both for the 44 cases of acute hepatitis ($\gamma=0.766$, $p<0.01$) and for the 15 cases of subacute fulminant hepatitis alone ($\gamma=0.852$, $p<0.01$). These results indicate that the values of α_2-HS-glycoprotein and the Normotest may be used for early identification of patients at high risk of death from viral hepatitis in whom aggressive therapy may be of value if instituted early enough.

9134 FOUR AUTOPSY CASES OF NEONATAL GIANT CELL HEPATITIS DIED SUDDENLY AND UNEXPECTEDLY FROM INTRACRANIAL HEMORRHAGE.

(Eng.) Sugai, M.; Kono, R.; Hiroki, T.; Kunita, Y.; Tokudome, S. (Tokyo Medical Examiner Office, Tokyo, Japan). *Acta Pathol. Jpn.* 28(1):185-191; 1978.

The cases of four patients with neonatal giant cell hepatitis who died unexpectedly from intracranial hemorrhage are presented. The patients were one boy and three girls, aged 37 to 50 days old. The postnatal growth rate was retarded in all four infants. At autopsy, the most prominent features of the liver were turbidity and an icteric color on the cut surface. Histologically, the lobular structure was irregular, and the normal appearance of parenchymal cell cords was lost. Multinucleate cells were present in the center of the lobules. Bile canaliculi were absent or poorly preserved within these cells, and bile stasis was evident. There was massive iron pigment deposition in hepatocytes and Kupffer cells in the periportal area. These changes were present in all cases, but their severity differed between cases. The weight of the brain was increased because of the presence of edema in all patients. In most cases, the hemorrhage occurred subdurally due to a massive intracerebral hematoma in the region of the centrum semiovale.

9135 CHANGES OF THE ERYTHROCYTE MEMBRANE AND SERUM LIPIDS IN ACUTE HEPATITIS AND LIVER CIRRHOSIS.

(Ger.) Pristautz, H.; Stubchen-Kirchner, H.; Fereberger, W. (Medizinische Universitatsklinik, Auenbruggerplatz 15, A-8036 Graz, Austria). *Wien. Med. Wochenschr.* 128(4):99-103; 1978.

Changes in erythrocyte membrane lipids and their possible relationship to serum lipids were studied in 33 patients with acute viral hepatitis, 11 patients with nondecompensated liver cirrhosis, and 11 healthy probands. The erythrocyte osmotic resistance (EOR) was normal in 10/33 patients with acute viral hepatitis and elevated in 23. The SGOT level was significantly increased in the hepatitis patients with elevated EOR compared with those with normal EOR (306 ± 45 mU/ml versus 147 ± 29 mU/ml). The SGPT, γ-glutamyltransferase, and alkaline phosphatase (AP) levels showed no correlation with elevated EOR. In the hepatitis patients with elevated EOR, the serum triglyceride level was noticeably but not significantly higher than that in the patients with normal EOR (210 ± 19 versus 158 ± 19 mg/100 ml), but the erythrocyte membrane cholesterol level was increased in 20/33 patients with elevated EOR and in only 1/33 patients with normal EOR. Among the cirrhotic patients, all four with elevated EOR showed increased erythrocyte membrane cholesterol levels, but there was no significant correlation between the serum enzyme levels and EOR. The lipid electrophoresis pattern was pathological in almost all hepatitis and cirrhosis patients with elevated EOR. The erythrocyte changes seen in viral hepatitis were already demonstrable a few days after onset of the symptoms, and always disappeared after the normalization of the transaminase levels. The findings indicate that the increased incorporation of cholesterol into erythrocytes in acute hepatitis is due to a disorder in hepatogenic apolipoprotein synthesis, rather than to excessive serum lipoprotein supply.

LIVER AND BILIARY TRACT

Chronic Hepatitis

9146 STUDIES OF LYMPHOCYTOTOXICITY IN ACUTE AND CHRONIC LIVER DISEASE. (Eng.) Warnatz, H.; Gutmann, W.; Rosch, W.; Hommel, G. (Institut und Poliklinik f. klinische Immunologie der Universitat Erlangen-Nurnberg, Postfach 35 60, D-8520, Erlangen, W. Germany). *Z. Immunitaetsforsch.* 153(5):435-449; 1977.

The cytotoxicity of lymphocytes from 14 patients with chronic active hepatitis, 8 with chronic persistent hepatitis, 11 with acute hepatitis B, 12 with rheumatoid arthritis, and 32 normal controls was studied by a microcytotoxicity assay using ^{125}I-iododeoxyuridine-labeled embryonal liver cells and Chang cells as target cells. Unfractionated lymphocytes of the peripheral blood from patients with chronic active hepatitis and rheumatoid arthritis showed a high frequency of cytotoxic activity; the lymphocytotoxicity in chronic active hepatitis was significantly increased in comparison with that in normal controls ($p<0.025-0.05$) at the effector cell to target cell ratios of 10:1 and 100:1. Specificity of the cytotoxic reaction to target cells could not be demonstrated. Addition of autologous serum to the cytotoxic assay blocked the lymphocytotoxicity in patients with chronic active hepatitis. A weak potentiating effect on lymphocytotoxicity was observed in patients with hepatitis B (HB) after addition of autologous serum. This reaction may be due to the presence of HB surface antigen (HBsAg) in the serum, since addition of HBsAg from other sources also increased the lymphocytotoxicity in HB patients ($p<0.05$). This effect was not observed either in HBsAg-positive or in HBsAg-negative patients with chronic active hepatitis or chronic persistent hepatitis.

9147 LIVER SPECIFIC AUTOANTIBODIES AND IMMUNOCOMPLEXES IN CHRONIC ACTIVE HEPATITIS.

(Ita.) Realdi, G.; Trevisan, A.; Losi, C.; Tremolada, F.; Roul, A. (Istituto di Medicina Clinica, Policlinico dell'Universita, 35100 Padova, Italy). *Boll. Ist. Sieroter. Milan.* 56(5):476-488; 1977.

A direct immunofluorescent technique was used to detect IgG, IgM, complement component C_3, and hepatitis B surface antigen (HBsAg) on the membrane of isolated hepatocytes obtained from biopsies in three groups of selected patients: 12 patients with inflammatory liver diseases (chronic persistent hepatitis, chronic active hepatitis, alcoholic hepatitis, or cirrhosis), 7 patients with chronic immune complex diseases without liver damage (systemic lupus erythematosus, rheumatoid arthritis, Sjogren's syndrome, or idiopathic cryoglobulinemia), and 6 control patients with nonhepatic diseases. Autoantibodies directed against a liver-specific protein (LSP) were identified by an indirect immunofluorescent technique using isolated rabbit hepatocytes. HBsAg was detected on the hepatocyte surface only in two cases of chronic persistent hepatitis, where surface IgG and IgM were absent. In all other patients with inflammatory liver diseases and in all patients with immune complex diseases, membrane IgG and IgM were found. Only in the patients with chronic active hepatitis (CAH) was C_3 found on the liver cell membrane. The pattern of fluorescence was linear-granular (at different levels of focus) in HBsAg-negative CAH and in alcoholic hepatitis, and granular in all the other cases. Anti-LSP antibodies were detected in the sera of two patients with serological features of autoimmune CAH. These results confirm a possible pathogenic role of liver-specific autoimmunity in some cases of CAH but also point out the presence of immune complexes in the livers of all patients with circulating immune complexes, whether or not these patients have liver damage. In all these diseases, a clearance function of hepatocytes for circulating immune complexes may be postulated. The presence of complement on the hepatocyte surface in chronic active liver disease suggests a possible pathogenic role of some immune complexes, probably those formed by LSP and its antibody.

9148 CLINICAL SIGNIFICANCE OF THE VARIATIONS OF THE PLASMA PROTEINS IN CHRONIC HEPATITIS.

(Ita.) Pugliese, V.; Picciotto, A.; Testa, R.; Mansi, C. (Istituto Scientifico di Medicina Interna, Universita di Genova, Genova, Italy). *Minerva Dietol. Gastroenterol.* 23(4):301-306; 1977.

Changes in serum proteins in chronic hepatitis are reviewed, and data on 193 patients with laparotomy- and biopsy-confirmed cases are presented. Transaminase, alkaline phosphatase, gammaglobulin, and prothrombin levels were evaluated in 45 patients with chronic persistent hepatitis (CPH) and in 148 with chronic aggressive (or evolutive) hepatitis (CAH). Transferin and α_1-antitrypsin levels were normal in 25/25 patients; the orosomucoide level was diminished in 12% of the cases; the α_2-macroglobulin level was increased in 56%; and the C'3 complement fraction was increased in 36%. The IgG, IgA, and IgM levels were increased in 36%, 40%, and 20% of the subjects, resp. The hepato-Quick test was altered in 65% of the patients. Serious deviations in fibrinoginemia were not observed. Fifty percent of the CAH patients had hypergammaglobulinemia, 45% had altered SGOT levels, 38% had altered SGPT levels, and 25% had altered alkaline phosphatase levels. The values for CPH patients were 25%, 30%, 25%, and 10%, resp. It is concluded that seroproteins alone are not a precise diagnosti or prognostic pool but are more useful when correlated with other clinical and morphological data.

9149 DYNAMICS OF STOMACH FUNCTION INDICES DURI GLUCOCORTICOID THERAPY FOR CHRONIC HEPATITIS AND LIVER CIRRHOSIS IN CHILDREN.

(Rus.) Deputatova, L. D. (Dept. Pediatrics, S. M. Kirov Gorkii Medical Inst., Gorkii, USSR). *Vopr. Okhr. Materin. Det.* 21(9):36-41; 1976.

9150 EFFECT OF GLUCOCORTICOIDS ON THE CLINICAL COURSE AND SOME INDICES OF NITROGEN METABOLISM IN PATIENTS WITH CHRONIC VIRAL HEPATITIS.

(Rus.) Melk, M. V. (Leningrad Inst. Pediatric Medicine, Leningrad, USSR). *Vrach. Delo* 6:137-139; 1976.

See also, 8828, 9079, 9080, 9085, 9086, 9096, 9126, 9129, 9130, 9131, 9137.

Alcoholic Liver Disease

9151 SERUM ALPHA-FETOPROTEIN IN ALCOHOLIC LIVER DISEASE. (Fre.) Dedieu, P.; Simon, J.; Chatal, J. F.; Buzelin, F.; Le Portz, J.; Miniconi, P. (Hopital Saint-Jacques, C.H.R., F44035 Nantes Cedex, France). *Gastroenterol. Clin. Biol.* 2(1): 7-14; 1978.

To determine the frequency and importance of the elevation of serum alpha-fetoprotein (AFP) level and to correlate these levels with clinical, biological, and anatomical-pathological findings, the serum AFP level was measured by radioimmunoassay in 210 patients with alcoholic liver diseases and in 139 controls. The serum AFP level was significantly elevated ($p<0.001$) in all three patient groups compared with the level in the controls (6.41 ± 1.40 ng/ml); it was >10 ng/ml in 14% of the 41 patients with alcoholic hepatopathy without cirrhosis (average, 9.2 ± 8.5 ng/ml), in 20% of the 146 patients with alcoholic cirrhosis, and in 15/23 patients with alcoholic cirrhosis and primary liver carcinoma. Serum AFP levels higher than 100 ng/ml were observed only in the patients with cirrhosis and the 21 with hepatomas. Among the patients with alcoholic cirrhosis, the serum AFP level was significantly elevated in all subgroups (compensated cirrhosis, isolated icterus, and ascites plus edema, $p<0.001$, and ascites plus edema plus icterus, $p<0.01$) except in the 29 patients with hepatic encephalopathy. There was no significant correlation between serum AFP levels and clinical manifestations, biochemical disorders, or histological lesions in any patients. In abstinent patients, serum AFP, after a transient elevation, tended to decrease progressively and return to normal level in 3 weeks. No correlation was found between serum AFP level and the survival time of the 21 patients with hepatoma. In the two patients with colangioma, serum AFP level was normal. It is concluded that, in patients with alcoholic cirrhosis, a serum AFP level >100 ng/ml or one that fails to decrease after abstinence strongly suggests the development of hepatoma.

9152 SERUM GAMMA-GLUTAMYL TRANSPEPTIDASE ACTIVITY IN HEPATOBILIARY DISEASE: ROLE OF CHRONIC ALCOHOLISM. (Fre.) Faivre, J.; Lamblot, J.; Michalet, J. P.; Massart, J. P.; Klepping, C. (Hopital General, 1, rue de l'Hopital, F 21033 Dijon Cedex, France). *Lyon Med.* 239(2):55-59; 1978.

Serum gamma-glutamyltranspeptidase (γGT) activity was studied in 30 normal subjects, 30 nonalcoholic patients without hepatobiliary disease, 79 patients with alcoholic liver cirrhosis (36 confirmed by biopsy), 34 chronic alcoholics without liver pathology, 49 patients with liver cancer, 30 patients with biliary duct obstruction, and 19 patients with acute benign viral hepatitis to determine its diagnostic value in liver disease. Levels of serum alkaline phosphatase, prothrombin, total bilirubin, and SGPT were also measured. Patients who had liver cancer and who were also chronic alcoholics had the highest γGT levels. All patients who were chronic alcoholics had elevated serum γGT levels; abstinence from alcohol resulted in a drop to normal levels, but if cirrhosis was present, return to normal levels was not consistently observed. In patients who were not chronic alcoholics, there was a marked correlation between levels of alkaline phosphatase and γGT; the correlation was not observed in alcoholics. Elevated γGT levels may indicate liver cancer in nonalcoholic patients, but the effect of alcohol consumption on γGT levels obscures the diagnostic value of γGT levels in alcoholics. Measurement of γGT should not be substituted for that of SGPT levels in patients with viral hepatitis since the enzyme is not as specific an indicator for these patients.

9153 THE IMMUNOPATHOLOGY OF ALCOHOLIC HEPATITIS: RECENT FINDINGS. (Ita.) Lovisetto, P.; Actis, G. C.; Marchi, L.; Ferraris, R.; Biarese, V. (Istituto di Medicina Interna, Universita degli Studi Torino, Torino, Italy). *Minerva Med.* 68(62): 4147-4151; 1977.

Recent findings on the immunopathology of alcoholic hepatitis are reviewed and discussed. Epidemiological studies show that 30% of heavy drinkers have liver problems associated with alcohol, and 10% develop liver cirrhosis in 1-12 yr. The hepatopathy of the alcoholic cannot be attributed exclusively to the toxic effects of ethanol; immunologic factors are believed to play a leading role. Hypergammaglobulinemia (IgG, IgA, and IgM) has been noted in patients with liver cirrhosis. Serum IgA from these patients binds to Mallory bodies, and in the initial phase of alcoholic hepatitis, it is possible to find serum antibodies to Mallory bodies. In patients with hepatopathy from alcohol, antibodies to albumin have also been found. It is hypothesized that the specific antigenicity of albumin in these cases has been altered by acetaldehyde, a product of ethanol metabolism. As many as 50% of these patients have been reported to have a reduced skin reactivity to dinitrochlorobenzene, and many have a diminished blast transformation of lymphocytes in response to phytohemagglutinin. A correlation has been found between the inability of a patient's lymphocytes to form spontaneous rosettes with sheep RBC and the degree of alcoholic liver damage in cases of cirrhosis. The leukocyte migration inhibition test shows that WBC from these patients produce migration inhibition factor in response to Mallory bodies or homogenates of healthy livers. It has been demonstrated that the supernatant fraction from a culture of patient lymphocytes incubated with Mallory bodies augments the incorporation of proline into collagen. The therapeutic implications are to treat the patient with corticosteroids that act against the immune system and with colchicine, an inhibitor of collagen formation.

9154 ENTERAL LIPID ABSORPTION IN PATIENTS WITH PORPHYRIA CUTANEA TARDA AND IN ALCOHOLICS.

(Ger.) Siklosi, C. (Universitats-Hautklinik Szeged, Szeged, Hungary). *Z. Hautkr.* 51(10):387-392; 1976.

Because lipid metabolism reacts promptly to any deterioration of hepatic and pancreatic function, enteral lipid absorption was investigated in 28 porphyria cutanea tarda (PCT) patients, in 21 chronic alcoholics, and in 20 dermatology patients without metabolic diseases (controls). Blood samples taken before as well as 2, 4, and 6 hr after the p.o. administration of Lipiodol Ultrafluid (an iodonated marker medium, 0.04 ml/kg body weight) w[illegible]d using potentiometry. Serum iodine levels decreased in the 6 hr following Lipiodol administration: by 82.14% in the PCT patients, 52.38% in the alcoholics, and 25% in the control group. The abnormally low value in the control group was attributed to the failure of some individuals to eat following Lipiodol intake. Thus, the Lipiodol test can provide information about the functional state of the small intestine mucosa only in cases of undisturbed digestive gland function. The advantages of the method include its simplicity, its very small probability of false positives, and it can provide information about the type of intermediary metabolism. However, this method provides reliable information only about the state of enteral absorption.

9155 COAGULATION FACTORS AND OTHER PLASMA PROTEINS DURING ABSTINENCE AFTER HEAVY ALCOHOL CONSUMPTION IN CHRONIC ALCOHOLICS.

(Eng.) Wallerstedt, S.; Cederblad, G.; Korsan-Bengtsen, K.; Olsson, R. (Sahlgrenska sjukhuset, S-413 45, Goteborg, Sweden). *Scand. J. Gastroenterol.* 12(6): 649-655; 1977.

Variations in the concentrations of different liver-synthesized coagulation factors and other plasma proteins were studied in the withdrawal period after prolonged alcohol consumption in 19 male chronic alcoholics. The mean duration of chronic alcoholism was 11 ± 9 yr. The duration of the last debauch was 25 ± 30 days, and the final daily ethanol consumption during the last debauch was 354 ± 97 g. The coagulation factor levels were generally within the reference limits. In fact, the mean levels of factors VIII, IX, and XII were above the upper reference limits, the values being 153 ± 12%, 155 ± 14%, and 214 ± 21%, resp., in samples taken 1-3 days after the end of the debauch and 167 ± 19%, 152 ± 14%, and 198 ± 20%, resp., in samples taken 7-10 days after the end of the debauch. The variables reflecting the fibrinolytic system, i.e., lysis area (148 ± 5 and 149 ± 4 mm^2 on day 1-3 and day 7-10, resp.) and plasminogen (16.6 ± 1.0 and 18.2 ± 0.7 U/ml, resp.), were generally within the reference range, as were antithrombin III (97 ± 5% and 112 ± 5%, resp.) and alpha$_2$-macroglobulin (77 ± 3% and 83 ± 4%, resp.). The number of platelets was often low, and the mean value at day 1-3 was just above the lower reference limit (reference range 150-350 x 10^9/l; mean level in patients 163 ± 13 x 10^9/l). However, the platelet adhesiveness was generally within the reference range. During the 1st week, a significant increase occurred in the factor XI activity, the antithrombin III level, and the number of platelets, the levels being 127 ± 13% (increasing from 96 ± 7% at day 1-3, $p<0.01$), 112 ± 5% ($p<0.05$), and 239 ± 23 x 10^9/l ($p<0.01$) on day 7-10, resp. In samples taken on day 1-3, other plasma proteins were usually within the reference limits. During the 1st week, a significant increase occurred in prealbumin (from 0.224 ± 0.012 on day 1-3 to 0.255 ± 0.011 g/l on day 7-10, $p<0.01$), transferrin (from 2.30 ± 0.12 to 2.59 ± 0.11 g/l, $p<0.05$), and complement components C3 (from 0.70 ± 0.03 to 0.89 ± 0.05 g/l, $p<0.01$) and C4 (from 0.211 ± 0.013 to 0.247 ± 0.017 g/l, $p<0.01$). Orosomucoid, IgG, IgA, and IgM levels decreased significantly during the same period ($p<0.05$, $p<0.01$, $p<0.01$, and $p<0.05$, resp.). A significant correlation between the fibrinogen concentration and ESR was observed ($p<0.01$). The data indicate that the protein-synthesizing capacity of the liver is well preserved in the patients in spite of a decade of chronic alcoholism.

9156 LIVER INJURIES IN ALCOHOLICS. (Eng.)

Abe, H.; Ikejiri, N.; Harada, K.; Ren-Pan, L.; Tanikawa, K.; Yokoyama, T.; *et al.* (Kurume Univ. Sch. Medicine, Kurume, 830, Japan). *Kurume Med. J.* 25(1):53-64; 1978.

The relationship of alcohol consumption to clinical findings, laboratory data, and liver histology was studied in 174 alcoholics. Histologically, there were 51 patients with minimal liver changes (M), 46 with fatty liver (F), 19 with fibrosis (Fi), 21 with alcoholic hepatitis (A), and 37 with cirrhosis (C). Alcoholic hyalin was seen in 4 patients with A and in 10 patients with C. Hepatomegaly was found in 108 patients, jaundice in 64, and esophageal varices in 13. Hepatomegaly was significantly ($p<0.025$) greater in patients with A and C than with M. The SGOT values were significantly higher ($p<0.005$) in patients with F, A, and C than with M and Fi. There was a significant ($p<0.001$) correlation between the SGOT level and both the lactate dehydrogenase (LDH) and creatinine phosphokinase (CPK) levels. SGPT values were also significantly higher in patients with A ($p<0.005$), F ($p<0.025$), and C ($p<0.05$) than with M and Fi. The SGOT/SGPT ratio was elevated in all groups. The SγGPT level was also markedly elevated in all groups and was significantly higher in patients with A ($p<0.005$), Fi ($p<0.01$), and F ($p<0.025$) than with M. The serum alkaline phosphatase level in patients with C was significantly higher ($p<0.05$) than in those with M. Compared with M, elevations in total serum bilirubin level, in the rate of indocyanin green retention, and in the serum gammaglobulin level in patients with A and C were significant ($p<0.025$, <0.05, and <0.05, resp.) as was the lowering of the serum albumin level ($p<0.05$). Total serum cholesterol level was significantly ($p<0.05$) lower in patients with C than with M. The serum malonic dialdehyde (MDA) levels were elevated in all groups. Hepatitis B surface antigen was positive in 11.5% of the cases, indicating involvement of the hepatitis virus.

No significant changes in age and duration distribution were found among the groups and, while no significant differences in the daily and total alcohol consumption were observed, the trend was for patients with Fi to have a long duration and relatively small quantity of alcohol intake and for patients with C to have a long duration and a large quantity of alcohol intake. The authors conclude that while the amount and duration of alcohol intake is closely related to cirrhosis, other factors must be considered in the pathogenesis of alcoholic liver disease. [illegible] h average MDA values recorded sug[illegible] of lipoperoxide in the development [illegible] liver injuries.

9157 CLASSIFICATION AND FREQUENCY OF ALCOHOLIC LIVER DAMAGE. (Ger.) Roschlau, G. (Medizinischen Akademie "Carl Gustav Carus," Fetscherstr. 74, DDR-8019 Dresden, E. Germany). *Dtsch. Gesundheitsw.* 32(16):721-724; 1977.

LIVER AND BILIARY TRACT

Cirrhosis

9160 CHANGES IN THE ACID-BASE EQUILIBRIUM IN LIVER CIRRHOSIS FOLLOWING PORTASYSTEMIC ANASTOMOSIS. (Ita.) Conte, G.; Semplicini, A. (Clinica Medica Generale II, Universita, Padua, Italy). *Recent. Prog. Med. (Roma)* 63(5):539-546; 1977.

Disturbances in acid-base equilibrium in hepatic cirrhosis induced by portasystemic anastomosis (respiratory alkalosis, metabolic alkalosis, and metabolic acidosis) are reviewed. The primary contributing factor to respiratory alkalosis after bypass surgery is the abnormally high serum level of ammonia, which stimulates the respiratory center and produces hyperventilation. The increase in serum ammonia is only in part lessened by a hypoprotein diet and by the use of antibiotics. Deteriorated liver functions also account for the increase in serum ammonia level as well as in the blood levels of lactate and pyruvate (probably further elevated by the increased activity of phosphofructokinase in an alkaline environment) and contribute to elevated levels of estrogen and progesterone. The respiratory alkalosis following bypass surgery can have secondary manifestations: reduction of the flow of blood to the brain (with symptoms of hyperammonemic encephalopathy), tetany and paresthesia due to decreased serum Ca levels. Respiratory alkalosis can be treated with chlorohydrated arginine. The most important cause of metabolic alkalosis after anastomosis is the depletion of potassium levels caused by the hypoprotein diet, impaired liver functions, and diuretic treatments. Diuretic treatments produce hyperaldosteronism because the loss of Na^+ and Cl^- contracts the extracellular volume and activates the renin-angiotensin system. The ultimate effects of the increase in aldosterone are increased elimination of K^+ and H^+, increased tubular reabsorption of HCO_3^-, diminished reabsorption of NaCl, and passage of extracellular H^+ into cells. Patients who have undergone anastomosis should be given KCl to decrease the incidence of postoperative metabolic alkalosis. Metabolic acidosis is a less frequent but more serious occurrence, caused by an increase in the production of hydrogen ions due to increased blood levels of lactate and pyruvate that result from profound derangements in carbohydrate metabolism. Decreased renal elimination of H^+ and an increase in H^+ concentration via the i.v. administration of acidic solutions also contribute to metabolic acidosis. If metabolic acidosis occurs after anastomosis, the use of acidic venous solutions and furosemide should be avoided.

9161 ALPHA$_1$-ANTITRYPSIN DEFICIENCY--A LITERATURE REVIEW AND A CASE REPORT OF A PA-

TIENT WITH CHRONIC OBSTRUCTIVE AIRWAYS DISEASE AND CIRRHOSIS. (Eng.) Coughlin, G. P.; van Deth, A. G.; Ey, G. T.; Grant, A. K. (Queen Elizabeth Hosp., Woodville, South Australia 5011, Australia). *Aust. N.Z. J. Med.* 7(4):400-403; 1977.

The case of a 52-yr-old man with alpha$_1$-antitrypsin deficiency (consistent with a state homozygous for the PiZ allele) is presented, and the literature concerning such cases is reviewed. The patient presented with a 12-yr history of increasing dyspnea on exertion and a productive cough. Clinical examination revealed severe obstructive deficit, panlobular emphysema, right ventricular hypertrophy, and an alpha$_1$-antitrypsin level of 50 mg/dl. Over the next 6 yr, he developed right heart failure, collapse of the thoracic vertebrae, renal failure, and mixed hepatitic-cholestatic liver function abnormalities (hepatitis B surface antigen was persistently negative). Postmortem examination revealed severe panlobular emphysema, extensive bullous changes throughout the lungs, patchy bronchopneumonia, mild fibrinous pleuritis, small amounts of thrombo-embolic material and occasional bone marrow emboli in the peripheral pulmonary arteries, marked right ventricular hypertrophy and dilatation, mild ischemic fibrosis of both ventricles, established micronodular cirrhosis with scattered areas of fatty change, numerous eosinophilic spherical intracytoplasmic PAS-positive and diastase resistant hyaline bodies in the hepatocytes, numerous intracytoplasmic inclusions bound by rough endoplasmic reticulum, mild vacuolar nephropathy, marked hypertrophy of the median lobe of the prostate, and slight dilatation of the ureters (suggesting bladder-neck obstruction as a cause for renal failure).

9162 CHOLESTATIC LIVER CIRRHOSIS WITH AUTOIMMUNE PHENOMENA IN IDENTICAL TWIN GIRLS. (Ger.) Kirchhof, M.; Dammermann, R.; Lindner, H.; Berg, P. A.; Kloppel, G. (DRK-Krankenhaus, Beim Schlump 84, 2000 Hamburg 13, W. Germany). *Therapiewoche* 28(6):1105-1106; 1978.

Cholestatic liver cirrhosis with portal hypertension and esophageal varices was found in two 45-yr-old identical twin sisters. Mitochondrial antibodies were sometimes present during the early stage of the disease, never during the final stage. The IgM level was not increased. A combination of antinuclear factors of nucleolar type, antibodies to smooth muscles, and cytoplasmic antibodies to kidneys, stomach, and thyroid cells were found. Nuclear antibodies were found in 4/12 children of the identical twins, but there were no manifest hepatopathies. The father of the identical twins had had liver disease (not specified) and pernicious anemia. The findings justify antibody tests in family members of patients with autoimmune chronic liver diseases.

9163 WHOLE GUT IRRIGATION WITH ISOTONIC MANNITOL SOLUTION IN TREATMENT OF GASTROINTESTINAL BLEEDING DUE TO CIRRHOSIS: A CONTROLLED STUDY. (Fre.) Hecketsweiler, P.; Colin, R.; Ouvry, D.; Galmiche, J. P.; Paillot, B.; Geffroy, Y. (Hopital Charles-Nicolle, F 76038 Rouen Cedex, France). *Gastroenterol. Clin. Biol.* 2(2):145-152; 1978.

Whole-gut irrigation with an isotonic mannitol solution (40 g/l) containing 17 mM NaCl, 13 mM KCl, and neomycin sulfate (250 mg/l) was used to treat gastrointestinal bleeding in 29 patients with liver cirrhosis, and the results were compared with those obtained in 30 age-, sex-, and symptom-matched controls treated without gut irrigation. All patients had portal hypertension secondary to alcoholic cirrhosis, and blood was present in the upper gastrointestinal tract although the hemorrhage source (such as esophageal varices or gastroduodenal lesions) was not always known. After fibroscopy examination and balloon tamponade insertion for hemorrhage, the control patients received gastric lavage and aspiration, neomycin (0.75 g), and lactulose (50 ml) and the study group received mannitol solution (5 l, 33 ml/min perfusion). Twelve hours later and every 12 hr during the period the patient was bleeding, 0.75 g neomycin and 50 ml lactulose were administered.
In the treatment group, only one patient developed hepatic encephalopathy (HE) in the 24 hr after treatment, whereas in the control group, five developed HE ($p=0.08$). Five and nine patients in these two groups resp., had HE before the study; regression of HE occurred in four of five in the first 24 hr after gut irrigation but in none of the control patients ($p=0.01$). After 24 hr of the study, 2/29 and 13/26 patients in the treatment and control groups, resp., had HE ($p<0.001$). In the control group, 3 patients died in the first 12 hr of the study and 10 more died of hemorrhage or HE within 12 days of admission. In the treatment group, only four patients died within the 12-day period ($p<0.02$). The duration of hemorrhage was not significantly different in the two groups, but the number of units of blood required to maintain a hematocrit of 35% was significantly less ($p<0.02$) in the treatment group. Of 18 controls and 22 treatment patients who entered the study without ascites and who were alive on the 7th day of the study, 8 and 2 patients, resp., developed ascites ($p<0.05$). Gut irrigation with an isotonic mannitol solution appears to prevent HE in cirrhotic patients with gastrointestinal hemorrhage and to improve prognosis.

9164 GASTRIC NARROWING WITH INTRALUMINAL FILLING DEFECT IN A 55-YEAR-OLD WOMAN. (Eng.) Margolies, M. N.; Galdabini, J. J.; McNeely, B. U. (Massachusetts General Hosp., Boston, MA). *N. Engl. J. Med.* 298(23):1301-1307; 1978.

A case record is presented concerning a woman with a life-long history of portal hypertension due to neonatal portal vein thrombosis who was admitted to the hospital with progressive epigastric burning pain, which was relieved promptly by vomiting. Seven months before admission, a radiologic abnormality in the gastric antrum had been detected after an episode of upper gastrointestinal bleeding. This had been treated with antacid, diazepam, atropine, and ferrous sulfate. After 4 months she began to experience the abdominal pain for which she was finally hospitalized. The patient had been under emotional stress. Laboratory findings were normal except for occult blood in the stool. Radiologic examination demonstrated gallstones and a stenotic lesion in the antrum that had progressed over a period of several months with the subsequent appearance of an intraluminal filling defect. Among the diseases considered and rejected in the differential diagnosis were Crohn's disease, benign gastric tumors, carcinoma of the gastric antrum, and lymphomas of the stomach. Gallstones were considered to be an incidental finding, and diagnosis was made of a cicatricial peptic ulcer with obstruction due to a foreign body retained in the stomach, a gastric bezoar. The bezoar was confirmed and removed endoscopically. It measured 2 x 1.5 x 1.1 cm, and was ovoid, firm, and externally greenish-black, with a gray interior. An irregular central cavity was filled with saprophytic bacteria and fungi. Microscopic examination showed it to be a phytobezoar, consisting of granular plant parenchyma and a few plant vascular elements.

9165 MALABSORPTION OF VITAMIN D IN MAN AND RAT WITH LIVER CIRRHOSIS.

(Eng.) Meyer, M.; Wechsler, S.; Shibolet, S.; Jedwab, M.; Harell, A.; Edelstein, S. (Dept. Internal Medicine D, Ichilov Hosp., 6 Weizmann St., Tel Aviv, Israel). *J. Mol. Med.* 3(1):29-37; 1978.

To localize the defect in vitamin D metabolism leading to the reduced circulating level of 25-hydroxyvitamin D observed in liver cirrhosis, vitamin D metabolism and absorption were studied in four patients with alcoholic or postnecrotic liver cirrhosis, three control patients, and 20 male Wistar rats with carbon tetrachloride-induced cirrhosis. In neither cirrhotic patients nor cirrhotic rats was there impairment of the conversion of i.v injected tritiated vitamin D to 25-hydroxyvitamin D. However, the level of cholecalciferol in the blood of both patients and cirrhotic animals that received tritiated cholecalciferol intragastrically was significantly lower at all times studied than that in the controls ($p<0.01$). It appears that impaired absorption of dietary vitamin D-3 may contribute to or be one of the etiologic factors in reducing the serum 25-hydroxyvitamin D levels in liver cirrhosis.

9166 FAMILIAL LIVER CIRRHOSIS IN PSEUDOHYPOPARATHYROIDISM IN YOUNG CHILDREN.

(Ger.) Thanner, F.; Kuhner, U.; Pfeifer, U. (Universitaets-Kinderklinik Wurzburg, Joseph-Schneider Strasse 2, 8700 Wurzburg, W. Germany). *Dtsch. Med. Wochenschr.* 103(12):519-523; 1978.

The appearance of pseudohypoparathyroidism (PHPT) in infancy has not been described previously, nor has the combination of PHPT and severe congenital liver disease. Two cases of this nature are described: two girls whose mother had PHPT developed PHPT with congenital liver damage. The first girl developed icterus on the fourth postnatal day, and was hospitalized at 2 months for persistent icterus and dystrophy. She was rehospitalized at 2 yr with hepatomegaly and splenomegaly, hypocalcemia, hyperphosphatemia, thrombocytopenia, and possible tetany. Laparoscopy showed postnecrotic hepatic cirrhosis with beginning portal hypertension. Histology of hepatic tissue demonstrated almost complete cirrhosis in some areas, areas of fibrosis, hyaline single cell necrosis, intracellular fat accumulation, and siderin present in parenchyma and stellate cells. Mesenchyme activity showed that the process was continuing. The child died at 4 yr following internal hemorrhage, despite treatment with calcium and vitamin D. The second girl, with prenatal dystrophy, was shown to have fatty liver deposits, isolated hyalin liver necrosis, and centrilobular multinuclear giant cells at birth. The course of the disease in this child was similar to that in her sister. Therapeutic administration of dihydrotachysterol, vitamin D, and calcium improved the state of the disease only transiently. Liver biopsy at 1.5 yr demonstrated the presence of "ectoplasmic vacuoles" by electron microscopy. The authors suggest that this combined disorder in calcium and liver metabolism may be the result of a genetic defect, as known metabolic or inflammatory cell diseases were excluded.

9167 ACUTE RENAL INSUFFICIENCY DUE TO NECROSIS OF THE RENAL MEDULLA IN CIRRHOTIC PATIENTS.

(Fre.) Dequiedt, P.; Dequiedt, F.; Vanhille, P.; Raviart, B.; Lambert, P.; Mouton, Y.; *et al.* (Hopital G. Dron, 59208 Tourcoing, France). *Lille Med.* 21(8):674-678; 1976.

The frequency, clinical profile, differential diagnosis, pathology, and treatment of acute renal insufficiency due to medullary necrosis of the kidneys and associated with liver cirrhosis are reviewed, and clinical profiles of three male patients (ages 54, 45, and 47 yr, resp.) are given. Insufficiency, which occurs in 2% of cirrhotics, is usually of sudden onset with oliguria accompanied by a severe infection. Two of the three patients had prodromal symptoms: pain and fever in one case and urinary infection and hematuria in the others. All three patients had accompanying lumbar pain, but icterus was present in only two. Plasma creatinine and urea levels were elevated, and the Na^+/K^+ ratio was >1. Correction of the acid-base balance and administration of antibiotics were used to treat the patients; however, two died on the 11th and 12th days, resp., following onset of renal insufficiency. Pathology other than kidney necrosis (acute pancreatitis, hematological interstitial nephritis, and acute tubulonephritis) can be the cause of acute renal insufficiency in chronic liver cirrhosis. Acute renal insufficiency of an apparent organic cause accompanied by septicemic infection in a cirrhotic patient should indicate the diagnosis of kidney necrosis. Changes in the kidney circulation during liver cirrhosis lead to medullary necrosis and thrombosis.

9168 SERUM CONCENTRATIONS AND URINARY EXCRETIONS OF ZINC IN CIRRHOSIS, NEPHROTIC SYNDROME AND RENAL INSUFFICIENCY.

(Eng.) Lindeman,

R. D.; Baxter, D. J.; Yunice, A. A.; Kraikitpanitch, S. (Veterans Admin. Hosp., 921 N.E. 13th St., Oklahoma City, OK 73104). *Am. J. Med. Sci.* 275(1): 17-31; 1978.

Serum Zn concentrations were measured in 12 patients with cirrhosis, 23 patients with nephrotic syndrome, and 13 patients with renal insufficiency to document the frequency of low serum Zn concentrations and to define the importance of urinary loss of Zn in the Zn deficiency commonly seen in these patients. Multiple correlations between the urinary zinc and protein excretions, and the patterns of binding between added radiozinc and serum and urine proteins determined by column chromatography and polyacrylamide gel electrophoresis were used to determine differences between the patients and 16 normal controls. The mean serum Zn concentrations were 90, 76, 66, and 49 μg/100 ml in normal, azotemic, nephrotic, and cirrhotic subjects, resp., the latter two values being significantly different ($p<0.01$) from the normal value. The mean 24-hr urinary Zn excretion was increased in the cirrhotic ($p<0.05$) and nephrotic patients relative to controls. In the azotemic group, the mean urinary Zn excretion was lower than in controls. No correlation ($r=0.097$) was found between serum Zn concentrations and urinary Zn excretions in the four groups combined, nor was there a significant relationship between serum Zn concentration and urinary protein excretion ($r=0.272$). There was a significant positive correlation ($r=0.340$, $p<0.05$) between serum Zn and albumin concentrations in the four groups combined but not for any individual patient group. In the nephrotic patients, there was a significant correlation between urinary Zn and protein excretions of ($r=0.431$, $p<0.05$). Sephadex G-200 gel chromatographic patterns for the sera and urine of controls and cirrhotic patients were similar except that, in the patients, peak II (containing albumins and prealbumins) was decreased. The patterns for the other two patient groups were less consistent, but both nephrotic and azotemic patients showed significant ($p<0.001$) increases in serum peak III (containing low molecular weight proteins, polypeptides, and amino acids) when compared with normal subjects. Polyacrylamide gel electrophoresis showed the mean percentage of radiozinc added to the serum that bound in the albumin peak was 95, 76, 47, and 63% in normal, cirrhotic, nephrotic, and azotemic patients, resp. The current study adds to the available data on Zn deficiency in cirrhotic, nephrotic, and azotemic patients but it remains unclear whether the low serum Zn concentrations are indicative of true clinical or subclinical Zn deficiency or simply reflect a decrease in available Zn-binding proteins or prealbumin.

9169 TUBULAR RENAL ACIDOSIS DURING LIVER CIRRHOSIS.

(Ita.) Triolo, R.; Carelli, E.; D'Alessio, R.; Italiano, F. (I Divisione di Medicina Generale, Ospedale Martini, Torino, Italy). *Minerva Med.* 68(53):3627-3642; 1977.

To investigate the behavior of the acid-base equilibrium in cirrhosis of the liver and to determine the effects of this disease on tubular renal functions, blood and urine analyses were made in 23 patients with liver cirrhosis. SGOT, SGPT, LDH, alkaline phosphatase, protein, bilirubin, glucose, calcium, phosphorus, sodium, potassium, chlorine, ammonia, bicarbonate, creatinine, and pH levels were determined. Patients were divided into three groups: seven patients with plasma pH <7.37 (group 1), four patients with a loss of bicarbonate (group 2), and two patients with plasma pH <7.37 without a loss of bicarbonate (group 3). The plasma analyses showed that the bicarbonate level was low i all three groups, with levels in group 3 being the lowest. Ammonia levels were normal in group 3 and raised in groups 1 and 2. Sodium was normal in groups 2 and 3 and low in group 1. Phosphorus was normal in patients with acidosis and loss of bicarbonate but low in the other patients. The bilirubin level was high in groups 1 and 2. The urine analyses revealed that ammonia levels were normal in all three groups. The acidity was normal in groups 1 and 3 but low in group 2. The bicarbonate filtrates were reduced in groups 1 and 3 and in patients with tubular renal acidosis type II complete, but it was raised in patients with tubular renal acidosis type II incomplete. The percentage of reabsorbed bicarbonate was reduced in group 2. The loss of sodium via the urine was greatly augmented in all three groups. It was calculated that 18 of the patients had supercompensated metabolic acidosis, and 5 had normally compensated metabolic acidosis.

9170 ELECTIVE DECOMPRESSION OF ESOPHAGEAL VARICES BY DISTAL SPLENO-RENAL BYPASS USING WARREN'S METHOD.

(Fre.) Mosimann, R.; Loup, P. (Centre Hospitalier Universitaire Vaudois, 1011 Lausanne, Switzerland). *J. Chir. (Paris)* 114(3): 175-184; 1977.

The results of treatment by splenorenal bypass in 22 patients with hemorrhaging esophageal varices related to liver cirrhosis and portal hypertension are presented. The cirrhosis was due to alcohol in 12 patients, to hepatitis in 8, to primary biliary cirrhosis in 1, and to alcoholic steatosis in 1. A termino-lateral anastomosis of the splenic and renal veins was performed in 12 patients (Warren's original method), and a termino-terminal anastomsis with ligature of the renal vein before the branching of the suprarenal and gonadal veins was performed in 10 patients. Two patients died postoperatively, one of hemorrhage from a duodenal stress ulcer and the other in hepatic coma following two reoperations for thrombosis of the shunt. Stenosis of the shunt occurred in another patient who survived but required portacaval anastomosis to control massive new hemorrhaging. Retrogastric lymphocele requiring drainage complicated the postoperative course of a fourth patient. Barium transit studies carried out in 17/20 surviving patients indicated disappearance or decrease of the esophageal varices in 13. In addition to the two patients who died postoperatively and the survivor who rebled, two other survivors hemorrhaged again, one at 6 months (autopsy revealed thrombosis of the portal vein and erosive gastritis, but the shunt was patent) and one after many months following an episode of alcohol abuse. No other patients rebled. In addition to this one late death, four other patients died during the follow-up period, all due to hepatic insufficiency. Twelve patients who had been followed for 6 months to 7 yr (average 2.5 yr) were still alive. One of the survivors had temporary encephalopathy in the early postoperative period. This operation is useful in treating portal hypertension when there is satisfactory portal blood flow, but it is contraindicated in the case of greatly reduced or inverted portal flow or in case of ascites or marked stasis of the splanchnic or retroperitoneal lymphatic network.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

9174 WHEN CHOLECYSTECTOMY? (Eng.) Naitove, A. (Dartmouth Medical Sch., Hanover, NH). *Hosp. Pract.* 13(6):121-128; 1978.

Factors that should be considered in determining which patients should undergo cholecystectomy are discussed. Acutely ill patients with an increased risk of operative mortality should avoid cholecystectomy. In patients with classic symptoms of chronic cholecystitis and radiologically demonstrated gallstones or a nonfunctioning gallbladder, elective cholecystectomy should be carried out provided there are no medical contraindications (including those imposed by old age). Previous studies have shown that severe complications (acute cholecystitis, cholangitis, jaundice, pancreatitis) occur in these patients when surgery is not carried out. Observation of asymptomatic or very mildly symptomatic patients has shown that gallbladder disease often does not progress in a predictable way from asymptomatic to mildly symptomatic to severely symptomatic to complicated; many patients are symptom-free from the initial diagnosis by cholecystography until the day a complication appears. The author's experience suggests that patients with symptoms of cholelithiasis that cannot be ascribed to any other cause, but which cannot be explained by any diagnostic procedure, should undergo surgery for suspected occult gallstone disease. Thus, elective cholecystectomy should be carried out in (a) patients with symptoms and radiological evidence of gallstones, (b) asymptomatic patients with radiologic evidence of gallstones, and (c) patients with symptoms but without radiologic evidence of disease. Since acute attacks of cholecystitis will subside in about 75-80% of patients, the primary test is to identify the optimal time for surgical intervention. In patients in whom advanced age is not a factor, in whom the diagnosis of acute cholecystitis is relatively certain, and for whom cholecystectomy is the inevitable choice of definitive treatment, operation should often be performed after 2 or 3 days of hospitalization and medical management. For older patients who may have other debilitating diseases or for those in whom further diagnostic workup is indicated, elective surgery 6-8 weeks later may be preferable. In patients in whom symptoms either do not improve or worsen during the first 48 hr after the onset of symptoms, emergency surgery is indicated.

9175 BACTERIAL FLORA OF THE SMALL INTESTINE AND BILE ACID METABOLISM IN PATIENTS WITH HEPATICO-JEJUNOSTOMY ROUX-EN-Y. (Eng.) Nielsen, M. L.; Justesen, T.; Lenz, K.; Nielsen, O. V.; Jensen, S. L. (31 Sofievej, DK-2900 Hellerup, Denmark). *Scand. J. Gastroenterol.* 12(8):977-982; 1977.

To determine whether ascending biliary tract infection from an intestinal blind loop with bacterial overgrowth could result in the polymicrobial flora seen in the bile of patients with hepaticojejunostomy, duodenal and jejunal bacterial flora and bile acid metabolism were investigated in 14 patients with Roux-en-Y hepaticojejunostomy. Duodenal aspirates were normal in seven patients, whereas abnormal bacterial flora were found in the other seven. The jejunal aspirate, taken in the most proximal part of the jejunum at the site of the entero-entero anastomosis, was normal in only one patient. The difference between the number of abnormal duodenal and abnormal jejunal aspirates was significant ($p<0.05$). Total bile acid concentrations in jejunal aspirates at the anastomosis were low in half the patients (<5 mM). Free (deconjugated) bile acids were found in only one patient, and only trace amounts were present. Free bile acids and an elevated glycine/taurine ratio (6.8) were found in one patient each. The 1-^{14}C-cholyl-glycine breath test was abnormal (>3% of dose expired as $^{14}CO_2$) in five patients, and abnormal ^{14}C output in stools (>5%) was observed in three patients. It is concluded that Roux-en-Y hepaticojejunostomy causes abnormal bacterial flora in the proximal jejunum of almost all patients, whereas alterations in bile acid metabolism are less frequent.

9176 INVESTIGATIONS ON ALBUMIN EXCRETION BY THE LIVER INTO THE BILE. I. POSTOPERATIVE ALBUMIN EXCRETION INTO THE T-DRAINAGE BILE. (Ger.)

Rogos, R. (Kreiskrankenhaus, Leipziger Str. 55, DDR-74 Altenburg, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 38(1):21-26; 1978.

The albumin level was determined by radial immunodiffusion and disc electrophoresis in 134 T-drain bile samples from 62 patients who underwent surgery for cholelithiasis, choledocholithiasis, cholecystitis, and cholangitis. The albumin concentration in the bile of these patients averaged 83.3 ± 61.2 mg/100 ml on postoperative day 1, 37.2 ± 34.7 mg/100 ml on day 3, and 23 ± 22.8 mg/100 ml on day 5. The albumin excretion rate was 228.8 ± 191.1 mg/day on day 1, 118.0 ± 96.7 mg/day on day 3, and 86 ± 86.2 mg/day on day 5. Albumin accounted for 41.8% of the total protein on day 1, for 39% on day 3, and for 40.8% on day 5. Compared with a normal albumin catabolism of 12 g/day, the postoperative albumin loss in the T-drain bile is negligible.

9177 EXCRETION OF METRONIDAZOLE IN HUMAN BILE: INVESTIGATIONS OF HEPATIC BILE, COMMON DUCT BILE, AND GALLBLADDER BILE. (Eng.)

Nielsen, M. L.; Justesen, T. (31 Sofievej, DK-2900 Hellerup, Denmark). *Scand. J. Gastroenterol.* 12(8):1003-1008; 1977.

To investigate the possible value of metronidazole (MNZ) in the treatment of biliary tract infections, MNZ excretion after i.v. injection (500 mg) was studied during surgery in 11 patients without biliary tract disease, 17 patients with gallstones with a normal common duct and normal gallbladder function, 22 patients with gallstones with a normal common duct and loss of gallbladder function, and 5 patients with common duct stones, common duct obstruction, and jaundice. Excretion of MNZ (2 g, p.o.) in hepatic bile was also determined in three other patients following surgery; MNZ appeared rapidly in hepatic bile, and throughout the 17-hr observation period almost identical concentrations of MNZ were found in serum and hepatic bile. In the patients with a normal biliary tract given an i.v. MNZ injection, significantly higher concentrations of MNZ were found in gallbladder bile than in serum ($p<0.01$). In patients with gallstones and preserved gallbladder function, no differences were found between the MNZ concentrations in the serum, common duct bile, and gallbladder bile. In patients with gallstones and loss of gallbladder function, no differences were found between the MNZ concentrations in the serum and in common duct bile, whereas the MNZ concentration in gallbladder bile was significantly lower than that in the serum and common duct bile ($p<0.01$). When MNZ concentrations in gallbladder bile were compare significant ($p<0.01$) differences were found between all three groups of patients: the highest concentrations were found in normal gallbladders and the lowest concentrations were found in nonfunctional gallbladders. In 9 of 14 patients with a blocked cystic duct, no MNZ was detected in gallbladder bile and in the remaining 5 patients, a concentration of 43-63% of the MNZ in serum was found. Thus, MNZ concentrations in gallbladder bile were significantly ($p<0.01$) lower than MNZ concentrations in both serum and common duct bile, whereas no significant difference was found between serum and common duct bile. In eight patients with a patent cystic duct, no significant differences were found between MNZ concentrations in serum, common duct bile, and gallbladder bile. Common duct bile MNZ concentrations in the patients with common duct obstruction varied from 56% to 99% of the corresponding serum MNZ concentration. I.v. MNZ would be useful in the chemotherapy of cholangitis.

9178 CARCINOMA OF THE PAPILLA OF VATER: A REVIEW OF FIFTY-SEVEN CASES. (Eng.)

Schlippert, W.; Lucke, D.; Anuras, S.; Christensen J. (Dept. Medicine, Univ. Iowa, Iowa City, IA 52242). *Am. J. Surg.* 135(6):757-762; 1978.

Experience with 57 cases of carcinoma of the papil of Vater are reviewed to determine the relative success of various kinds of surgery and to define those clinical characteristics that suggest the diagnosis and that correlate with survival, papilliation, and cure. The relative frequencies for both pancreatic and papillary malignancies increas little since 1940, with approximately 13-16 cases of pancreatic malignancy occurring for each case of papillary tumor. The most common presenting complaints were weight loss in 94% and jaundice in 91%. Hepatic enlargement was discovered on physical examination in 64%. Of 47 upper gastrointestinal contrast studies, 26 were interpreted as normal. The 21 abnormal results included abnormalities of the second part of the duodenum in 12 patients, extrinsic pressure on the stomach or duodenum in 5, the "inverted three" sign in 1, and partial duodenal obstruction by an annular lesion in 1. Endoscopic retrograde chola giopancreatography confirmed the diagnosis in the two patients in whom it was carried out. Percutaneous transhepatic cholangiography was performed in three patients and was abnormal in all, but celiac angiography was noncontributory in the two patients in whom it was performed. Local resection was carried out in seven patients. One patient is alive and well 12 yr after resection, and another died during the immediate postoperative period; the mean survival in the remaining cases was 21.3 ± 2.0 months (range 1.5-58 months). No metastases were found at the time of resection in any of these seven cases. A bypass procedure was performed initially in 16 patients. Metastases were noted in six cases. There were three operative deaths, and the mean survival of the remaining patients was 13.1 ± 1.3 months (1.5-41 months). A Whipple operation was performed initially in 31 patients, and metastases were found in 9 cases. There were seven operative deaths. Three patients are still alive 6, 6, and 84 months postoperatively. Two patients died of unrelated diseases. Mean survival excluding two current survivors whose survival is less than the median was 24.1 ± 1.2 months (11-53 months). When patients with metastases were considered separately, those who had a Whipple operation survived significantly longer than those who had a bypass operation ($p<0.05$). The Whipple procedure is probably the better operation for carcinoma of the papilla of Vater. Local resection in the absence of metastases offers a chance for cure and a survival rate that do not differ from those of the Whipple operation, although 50% of the cases in this series who underwent resection needed subsequent palliative surgery.

9179 CARCINOMA ARISING IN A CONGENITALLY DILATED BILIARY TRACT: REPORT OF A CASE AND REVIEW OF THE LITERATURE.

(Eng.) Kagawa, Y.; Kashihara, S.; Kuramoto, S.; Maetani, S. (Tenri Hosp., Tenri, Nara, Japan). *Gastroenterology* 74(6): 1286-1294; 1978.

The case of a patient with carcinoma arising in a congenitally dilated biliary tract is reported, and the 47 cases in the world literature are reviewed. The patient was a 57-yr-old woman with a 5-yr history of episodes of characteristic symptoms of cholangitis. Endoscopic retrograde cholangiopancreatography disclosed a markedly dilated common duct, 20 mm in diameter in the intrapancreatic portion and 40 mm in the supraduodenal portion. The upper part of the common duct and the gallbladder were not fully visualized because of incidental incompetence of Oddi's sphincter. Percutaneous transhepatic cholangiography revealed dilated intrahepatic ducts and obstruction near the confluence of the hepatic ducts. Selective angiography revealed irregularity and tumor stain of the branches of the hepatic artery, which derived from the superior mesenteric artery. At surgery, the gallbladder was distended, and the common duct was dilated, having a diameter of 50 mm; neither contained stones. A papillary tumor was found filling the common bile duct lumen. Biopsy of the lesion confirmed papillary adenocarcinoma. The common duct, common hepatic duct, gallbladder, and regional lymph nodes were resected, and Roux en-y hepaticojejunostomy was performed at the bifurcation of the hepatic ducts. The patient has been asymptomatic for 30 months postoperatively. Drip infusion cholangiography at 4 and 10 months after surgery revealed dilated intrahepatic ducts. There was no evidence of obstructive jaundice, indicating that the dilatation of the intrahepatic ducts was congenital and not secondary to obstruction. A review of the literature suggests that the association of carcinoma with congenital biliary ductal dilatation is more frequent than is commonly recognized. Carcinoma may arise in either the extrahepatic or intrahepatic ducts. Primary excision of choledochal cysts is advisable, to prevent the risk of later malignant change.

9180 LIPOPROTEIN METABOLISM IN CHOLESTASIS.

(Ger.) Patsch, W. (Medizinische Universitatsklinik, Anichstrasse 35, A-6020 Innsbruck, Austria). *Acta Med. Austriaca* 4(Special Issue): 86-87; 1977.

The relationships between lipoprotein-X (LP-X) and lecithin cholesterol acyltransferase (LCAT) activity were studied in three patients following the surgical removal of bile flow obstruction. The LCAT activity reached 3-4 times the normal value on the 4th postoperative day, while the concentration of LP-X_2, decreased rapidly. On the 6th postoperative day, the concentration of LP-X, also decreased rapidly. When LP-X_1 and LP-X_2 were incubated separately in normal plasma at 37 C, the half-life of LP-X_1 was 24 hr and that of LP-X_2 9.5 hr; the difference may be due to different apolipoprotein levels in the two compounds. During the reduction of the LP-X concentration in the medium, there appeared a high-density lipoprotein (HDL_2), which suggests that the decomposition of LP-X is mediated by an acyltransferase. The findings indicate the existence of a relationship between LP-X and LCAT.

9181 INDUCTION OF BILE ACID GLUCURONIDE FORMATION IN CHILDREN WITH INTRAHEPATIC CHOLESTASIS.

(Eng.) Frohling, W.; Stiehl, A.; Czygan, P.; Liersch, M.; Kommerell, B.; Rotthauwe, H. W.; *et al. In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* (Baltimore: University Park Press): 101-104; 1977.

The effect of phenobarbital on intrahepatic cholestasis was reevaluated in three children with intrahepatic cholestasis, with special regard to a possible induction of bile acid glucuronide formation. The patients were treated with 0.1-0.14 g phenobarbital daily for at least 14 days. Phenobarbital caused an improvement of cholestasis, the disappearance of jaundice, and a decrease in serum bile acid concentrations of 60% (from 119 to 41 µg/ml) in all patients; nonsulfated, nonglucuronidated bile acids and bile acid sulfates were markedly reduced, whereas the decrease of glucuronides was much smaller (glucuronides accounted for 14% of the serum bile acids before treatment and for 27% after treatment). Biliary bile acid excretion increased by 47% (78% for nonsulfated, nonglucuronidated bile acids, 62% for sulfates). Bile acid glucuronides increased by 122%, accounting for 12% of the bile acids before treatment and for 18% after treatment. The percentage of glucuronides of the different bile acids in bile ranged from 12-29% before treatment and was increased by phenobarbital for all bile acids investigated. Remarkably high rates of bile acid glucuronides, accounting for 40-60% in two children, were found for Δ-5-cholenic acid and lithocholic acid after treatment, suggesting a correlation between extensive glucuronidation and the disappearance of these highly toxic bile acids after phenobarbital treatment. Bile acid sulfate excretion in bile decreased after phenobarbital; 25% of bile acids were sulfated before treatment and 6% after treatment. Urinary bile acid excretion decreased by 45% after treatment, due to the lowered serum bile acid concentrations. Sulfated and nonsulfated, nonglucuronidated bile acids were similarly reduced, whereas the excretion of glucuronides increased by 136%. The alteration in the bile acid pattern after phenobarbital, with an increase in the percentage of serum, bile, and urinary bile acid glucuronides and an increase in the absolute amounts of glucuronides excreted in bile and urine, strongly suggests an increased formation of bile acid glucuronides after phenobarbital treatment.

9182 CONGENITAL CYSTIC DILATATION OF THE INTRA- AND EXTRAHEPATIC BILIARY TRACT.

(Fre.) Bloch, P.; Dimitrov, N.; Eidesheim, D.; Clavert, A.; Christmann, D.; Kim, K.; *et al.* (Service de Radiologie, C.H.U. F67005 Strasbourg Cedex, France). *J. Radiol. Electrol. Med. Nucl.* 58(12):839-840; 1977.

A case of a cystic dilatation of the intra- and extrahepatic biliary tract in a 12-yr-old girl is reported. She was hospitalized for a painful abdomen syndrome that was diagnosed as acute pancreatitis. Her past medical history included an episode of icterus at the age of 4 yr and two other hospitalizations for painful abdomen. No abdominal mass was palpated. X-rays showed an enlargement of the retrogastric space and compression of the stomach. I.v. cholangiography revealed the cystic dilatation of the biliary tract. At surgery, the latter diagnosis was confirmed and two cysts were found, one a 5-cm cyst of the gallbladder and the other a cyst of the common hepatic duct. The pancreas was hard and enlarged, which accounted for the enlargement of the retrogastric space. The long-term results of surgical treatment have been excellent.

9183 MIRIZZI'S SYNDROME AS A SPECIAL FORM OF OBSTRUCTIVE JAUNDICE.

(Ger.) Heil, T.; Belohlavek, D. (Zentrum fur Operative Medizin der Universitat, Steinhovelstrasse 9, D-7900 Ulm/Donau, W. Germany). *Chirurg* 49(1):57-59; 1978.

Mirizzi's syndrome (isolated stenosis of the hepatic duct) was diagnosed in three patients. Recurrent fever and right epigastric pains were the first symptoms. Two patients had jaundice. Endoscopic retrograde cholangiography was performed in two cases; it demonstrated Mirizzi's syndrome in both. Gallstones were found in the cystic duct in two patients and in the gallbladder in the third.

9184 HEPATIC NECROSES AFTER INFUSION CHOLANGIOGRAPHY.

(Ger.) Winckler, K. (Abteilung fur Gastroenterologie und Stoffwechselkrankheiten, Medizinische Universitatsklinik, Robert-Koch-Str. 40, 3400 Gottingen, W. Germany). *Dtsch. Med. Wochenschr.* 103(10):420-424; 1978.

Ten episodes of massive increase of transaminase levels accompanying liver necrosis were observed in seven patients (1 each with biliary tract disease, recurrent pancreatitis, cholelithiasis, hyperlipemia and minimal toxic liver damage, pyelonephritis, arteriitis, and pseudolupus erythematosus) following infusion of megluminioglycamide (Biligram; 10 ml in 5 cases, 200 ml in 2). In six patients, there was an increased alkaline phosphatase level without jaundice before the investigation, and a slight increase in the transaminase levels in three. After Biligram infusion, there was an abrupt increase in the SGPT level (range 98-2,202 U/1), and a lesser increase in the SGOT level, but the alkaline phosphatase level showed no major change. Abdominal pain, fever, erythema, or conjunctivitis were seen in three patients. Histologically, all patients showed centrilobular necrosis. Transaminase levels should be checked 2 days after infusion cholangiography; in patients showing definite increase, reexposure to the contrast agent should be avoided.

9185 BILE-DUCT OBSTRUCTION IN A 39-YEAR-OLD MA

(Eng.) Burhenne, H. J.; Galdabini, J. J. (Massachusetts General Hosp., Boston, MA). *N. Engl J. Med.* 297(19):1054-1059; 1977.

The case of a patient with bile duct obstruction and a discussion of the differential and clinical diagnosis are presented. The patient developed jaundice 1 week after receiving halothane anesthesi for herniorrhaphy. An ultrasound study demonstrate distended intrahepatic bile ducts. Upper gastrointestinal series and hypotonic duodenography helped rule out an obstructing pancreatic lesion. Endoscopic retrograde cholangiopancreatography revealed complete obstruction of the common hepatic duct 1 cm proximal to the insertion of the cystic duct. The contrast column at the point of obstruction showed a smooth, conical narrowing. Distal to the obstructed area, the common hepatic and common bile ducts appeared normal in caliber an contour, and the main pancreatic duct appeared normal. A ^{99m}Tc-sulfur colloid liver-spleen scan demonstrated nonhomogeneous activity throughout th slightly enlarged liver. The spleen was slightly enlarged, with relatively increased uptake. No marrow uptake was identified. Selective superior mesenteric and hepatic angiography disclosed that the hepatic artery was a branch of the superior mesenteric artery; the major branches of the superior mesenteric artery were patent, and films obtained during the venous phase were normal. There was a slightly nonhomogeneous hepatographic phase suggestive of dilatation of the biliary radicles. No tumor blush or abnormal vascularity was observed, and the portal vein was patent. Fine-needle transhepatic cholangiography revealed multifocal concentric narrowing of major hepatic ducts in the region of the porta hepatis, with dilatation of secondary intrahepatic radicles. Combining the findings from the retrograde study, the scan, and angiography led to the conclusion that there was a small mass in the porta hepatis above he neck of the gallbladder. Percutaneous transepatic cholangiography was the most diagnostic, showing the lesion from two sides. The preoperative diagnosis was an obstructing carcinoma t the porta hepatis, probably a cholangiocarcinoma. t exploration, a small tumor involving the proximal ortion of the common hepatic duct and extending p into the liver was found. Frozen-section examiation of the wedge-biopsy specimen revealed cords f tumor cells that had formed tubules with mucin ecretion. Cholestasis and bile duct proliferation ere observed in the adjacent liver. The anatomical iagnosis was adenocarcinoma of the hepatic ducts t the junction with the common hepatic duct.

186 BILE DUCT INJURIES FROM NON-PENETRATING ABDOMINAL TRAUMA IN CHILDHOOD. (Eng.) hmed, S. (Adelaide Children's Hosp., 72 King Wiliam Rd., North Adelaide, South Australia 5006, ustralia). *Aust. N.Z. J. Surg.* 46(3):209-212; 1976.

he cases of three children with bile duct injuries rom nonpenetrating abdominal trauma are presented. he first patient, a 2.5-yr-old girl, was admitted ith vomiting of bile-stained fluid. She was pale nd dehydrated, with multiple bruises, and was hought to be a battered baby. Abdominal signs ere equivocal, and initially she was managed conervatively, but on the 3rd day of hospitalizaion, she had signs of peritonitis. Surgical exloration revealed peritonitis and transection of he common bile duct. Continuity was established y performing a choledochoduodenostomy over a T-ube inserted through the common bile duct. The nd of the transected duct was sutured to the dudenal mucosa. A drain was placed to the site of nastomosis, and the wound was closed. The second atient was a 6-yr-old boy who presented with upper bdominal pain, vomiting, increased pulse rate, nd a blood pressure of 90/55 mm Hg after being it by a car. Abdominal tenderness, rigidity, and bsent bowel sounds were observed. At emergency aparotomy, a laceration of the inferior surface f the liver and transection of the common bile uct, which was identical with that in the first atient, were discovered. Choledochoduodenostomy as performed, and the surgical technique described n the first patient was adopted; this time, howver, the T-tube was inserted through the duodentomy. The third patient, a 5-yr-old girl who had been hit by a truck, presented with abdominal tenderness, rigidity, and absent bowel sounds. At surgery, a liver laceration and perforation in the common hepatic duct were found. The duct was not sutured, and a large drain was left *in situ*. All patients made satisfactory recoveries. Bile duct injuries due to nonpenetrating trauma present urgently when associated with liver laceration or other abdominal visceral injuries. When the duct injury is an isolated one, the ensuing clinical picture may be insidious. Surgical management is aimed at early recognition of the injury, followed by reconstruction of the biliary tract.

GENERAL

9208 VERNER-MORRISON SYNDROME: CLINICAL STUDY. (Fre.) Dupuy, R. (Hopital Beaujon, 100, av. du General-Leclerc, 92110 Clichy, France). *Ann. Gastroenterol. Hepatol.* 13(6):599-605; 1977.

The Verner-Morrison (V-M) syndrome that accompanies a tumor of the Langerhans' cells of the pancreas is reviewed. The tumor is the rarest of the pancreatic tumors and, since a report of 64 cases published in 1974, not many more have been added to the literature. The average age of patients with this tumor is 47 yr with an age range of 17-72 yr. The tumor secretes a hormonal factor that induces intestinal peristalsis, causing symptoms of abundan aqueous diarrhea. The diarrhea is accompanied by hypokalemia of 3.6-1.2 mEq and hypochlorhydria in 50% of the patients. Differential diagnosis o the V-M syndrome from Zollinger-Ellison disease i established by the ulcer and hyperchlorhydria in the latter and from carcinoids by the hypotension

d severe flushing of the skin in the latter. In
-35% of the V-M syndrome patients, a malignant
mor is responsible for the disease, and prog-
sis is poor; the cause of the V-M syndrome
; a benign adenoma of the pancreas in 41%
 the patients and pancreatic hyperplasia
 the remainder. Absence of a malignant tumor is
t an assurance of a good prognosis, since one-
ird of the patients with adenomas die of renal
sufficiency related to hypokalemia. Early di-
nosis and surgical excision of a malignant tumor
 subtotal pancreatectomy with restoration of the
ectrolyte balance with a benign tumor or hyper-
asia are the recommended treatments.

209 VERNER-MORRISON SYNDROME: MORPHOLOGICAL DATA DERIVED FROM HISTOENZYMOLOGY AND
STOIMMUNOLOGY. (Fre.) Martin, E. D.; Galain, A.;
otto, J.; Leclerc, J. P.; Ganter, P. (Hopital
toine-Beclere, 157, rue de la Porte-de-Trivaux,
141 Clamart, France). *Ann. Gastroenterol. Hepatol.*
(6):615-627; 1977.

 the basis of 91 cases of the Verner-Morrison
-M) syndrome (4 new cases, 87 from the litera-
re), the epidemiological, histological, physio-
gical, and immunological aspects of the syndrome
e reviewed. Both sexes are equally likely to
velop the V-M syndrome; the age range is 17-78 yr
th an average age of 46 yr. The V-M syndrome is
used by a tumor of the pancreas that is larger
an 3 cm in 78% of the patients. The tumor is
lignant in 62.5% of the patients; otherwise the
ndrome may be induced by an adenoma, polyadeno-
tosis, or hyperplasia of the pancreas. No ectopic
mors have been identified. Criteria for malig-
ncy are not based on cytological characteristics
nce the tumor cells are almost always regular
th little evidence of mitoses; it is based on the
esence of intravascular emboli and hepatic or
mph node metastases. Ultrastructural studies,
rformed in 17 cases reported in the literature and
 3 in the present series, show two populations of
cretory granules: one about 300 nm in diameter
d the other about 625 nm. Histochemical immuno-
uorescence studies reveal the presence of a vaso-
tive intestinal polypeptide (VIP) that has also
en found in bronchial carcinomas, a pheochromocy-
ma, and two ganglioneuroblastomas. In 50% of
mors in V-M patients, another hormone, the human
ncreatic hormone (HPP), has been found associ-
ed with VIP. The presence of VIP in tumors known
 be of nerve tissue origin may be evidence for
e neuroectodermal origin of the tumor cells that
use the V-M syndrome.

10 SECRETIN AND THE ZOLLINGER-ELLISON SYNDROME: RELIABILITY OF SECRETIN TESTS
) PATHOGENETIC ROLE OF SECRETIN. (Eng.) Stage,
 G.; Stadil, F.; Rehfeld, J. F.; Fahrenkrug, J.;
haffalitzky de Muckadell, O. B. (H. C. Andersens
vd. 47, 1553 Copenhagen V, Denmark). *Scand. J.*
stroenterol. 13(4):501-511; 1978.

 establish the reliability of secretin tests in
e diagnosis of the Zollinger-Ellison syndrome
(ZE), the effects of an i.v. infusion (1 clinical U (CU)/kg/hr) or injection (1 CU/kg) of secretin on serum gastrin concentrations were compared in 25 hypersecretors with verified ZE and in 19 patients with duodenal ulcer disease. Secretin infusion raised the serum gastrin levels in the ZE patients. The increase appeared within 15 min and lasted until termination of the infusion. The peak value of 128 ± 13.1% of basal (p=0.01) was reached after 30 min. In ulcer patients, the serum gastrin concentration increased only after termination of the infusion (to 120.5 ± 8.5% of the basal level, p<0.05). Differences in the serum gastrin level during infusion between the ZE and ulcer patients were not significant, but the levels 5 min after an i.v. bolus injection were significantly different (238 ± 40% and 132 ± 12% of the basal level in ZE and ulcer patients, p<0.01 and p<0.05, resp.). However, not all ZE patients responded to the injection, and there were overlapping results in the two groups of patients both after infusion and after bolus injection. Pre- and postoperative studies showed that total gastrectomy did not influence either the gastrin response to secretin or the serum gastrin level. Serum gastrin corresponded to the four gastrin components I-IV. No changes in the gastrin component pattern occurred after secretin administration in any patient. The serum secretin concentrations in 11 fasting unoperated patients and 5 gastrectomized ZE patients tested (5.6 ± 0.75 and 2.2 ± 0.8 pM, resp.) were higher than in 74 normal subjects (1.4 ± 0.2 pM, p<0.001). This result does not support the hypothesis that secretin release by acid entering the duodenum drives the gastrin release from gastrinomas, since exogenous secretin often failed to raise the serum gastrin concentration and since serum gastrin concentrations did not decrease after total gastrectomy. Because of the failure of some ZE patients to respond to the secretin test, a positive result is not sufficient to establish the diagnosis of ZE. The secretin test appears to have limited diagnostic value in ZE patients.

9211 REPORT ON THE UNITED STATES EXPERIENCE WITH CIMETIDINE IN ZOLLINGER-ELLISON SYNDROME AND OTHER HYPERSECRETORY STATES. (Eng.) McCarthy, D. M. (Natl. Inst. Arthritis, Metabolism and Digestive Diseases, Bldg. 10, Rm. 9D-15, Natl. Inst. Health, Bethesda, MD 20014). *Gastroenterology* 74(2, Part 2):453-458; 1978.

Experience with cimetidine in the treatment of 61 patients with the Zollinger-Ellison syndrome, encountered over a 2-yr period, is presented. Half the patients have been treated for over 1 yr. Two-thirds of the patients responded to 300 mg of the drug p.o. every 6 hr; others required up to 600 mg every 6 hr. In adequate doses, the drug was highly effective; it controlled pain and dyspepsia, restored weight, abolished diarrhea, and allowed healing of ulcers and other inflammatory conditions. Missed or reduced doses led to rapid return of symptoms. Progression of the basic neoplastic process, with associated secretory drive, was unimpeded. Patient acceptance of the drug was 100%, and apart from minor transient abnormalities, gynecomastia (5 cases) and liver dysfunction (3 cases), which resolved while treatment continued, no serious adverse effects were seen. Of 61 patients, 48 are still on the drug, 3 who were well controlled were also treated surgically, 5 died for reasons unrelated to therapy, and 5 had significant problems. The drug provides an alternative to total gastrectomy and can be recommended with confidence for the suitably selected patient.

9212 HISTOLOGICAL, HISTOENZYMOLOGICAL AND ULTRAMICROSCOPIC ASPECTS OF PANCREATIC TUMORS IN ZOLLINGER-ELLISON SYNDROME. (Fre.) Potet, F. (Hopital Beaujon, 100, bd du General-Leclerc, 92110 Clichy, France). *Ann. Gastroenterol. Hepatol.* 13(6):591-597; 1977.

Histological, histoenzymological, and ultramicroscopic features of the pancreatic tumors causing the Zollinger-Ellison (ZE) syndrome are discussed. The histochemical behavior of the tumor does not always parallel that of the gastrin cell from which it has been thought to arise. Characteristically, the gastrin cell shows argyrophilia by the methods of Grimelius and Sevier-Munger, fluorescence when exposed to formol, metachromasia with toluene blue at pH 5.5, and hematoxyline reaction with lead. The reaction found most consistently is argyrophilia, which identifies tumor cells with an endocrine origin. Ultrastructurally, the granulation typical of the gastrin cell is not observed in the pancreatic tumors. Unlike the normal gastrin cell, granules in the tumor cells are of variable density, irregular size, and not abundant. Immunochemically, the tumor cells react like the gastrin cells, since they react with antiserum marked with the isothiocyanate of fluorescein (indicating the presence of gastrin). In 20% of cases, there are two, three, or more types of secretions present, but secretion of gastrin predominates. The histogenesis of the tumors that cause the ZE syndrome is not well understood.

9213 NEW DATA ON METHODS FOR MORPHOLOGICAL EXAMINATION OF PANCREATIC GROWTHS IN ZOLLINGER-ELLISON SYNDROME. (Fre.) LaMarque, J. L.; Bruel, J. M.; Dondelinger, R.; Polge, D. (Hopital Saint-Eloi, 34059 Montpellier Cedex, France). *Ann. Gastroenterol. Hepatol.* 13(6):579-590; 1977.

Diagnosis by conventional x-ray and angiographic examinations of the pancreatic tumors that cause the Zollinger-Ellison (ZE) syndrome is discussed. The cause of the ZE syndrome is a small pancreatic tumor, often multiple, sometimes reduced to simple hyperplasia. The criteria for malignancy of these tumors is the presence of hepatic metastases. The metastases are highly vascular and can be readily diagnosed by selective angiography of the splenic and superior mesenteric veins. In the absence of hepatic metastases, the pancreatic tumors can be identified more readily if they are highly vascular. Selective arteriography of the gastroduodenal and dorsal pancreatic arteries will show the hypervascular pancreatic tumors. In the 20% of pancreatic tumors that are not highly vascular, diagnosis must be made by indirect signs such as compression of arteries and veins and lacunar x-ray images of the body of the pancreas. Usually, only large tumors will produce these signs. The use of sonography, scintigraphy, and tomodensitometry in the diagnosis of pancreatic tumors is also discussed.

Parasitology

9243 AMEBIASIS: EPIDEMIOLOGIC STUDIES IN THE UNITED STATES, 1971-1974. (Eng.) Krogstad, D. J.; Spencer, H. C., Jr.; Healy, G. R.; Gleason, N. N.; Sexton, D. J.; Herron, C. A. (Center for Disease Control, Atlanta, GA). *Ann. Intern. Med.* 88(1):89-97; 1978.

Seven investigations of suspected foci of amebiasis in the United States that were performed by the Center for Disease Control between October 1971 and June 1974 indicated that the disease was being vastly overdiagnosed by a number of laboratories. The problem encountered most frequently in these investigations was that WBC in the stool were identified as *Entamoeba histolytica*. Two laboratories found to be in error were in community hospitals, and one was at a teaching hospital associated with a medical school and a school of public health. Altogether, these three laboratories had been diagnosing about 1,200 cases of amebiasis a year for 20 yr. When amebiasis does occur, it is likely to be misdiagnosed. In one outbreak involving four cases and three deaths, amebiasis was not diagnosed until two patients had died and another was critically ill. Sporadic cases may be mistakenly diagnosed as ulcerative colitis and inappropriately treated with steroids. Stool examination for intestinal protozoa is difficult and requires a highly trained laboratory technologist. Because of this, serology should play an increasingly important role by detecting positive titers in patients with active intestinal amebiasis who might otherwise be treated for nonspecific ulcerative colitis. Endemic foci of amebiasis continue to exist in the United States as revealed by two of the investigations, which indicated that the disease was associated with poor sanitation and was transmitted by a person-to-person mode.

9244 BILIARY ASCARIASIS PRESENTING IN THE UNITED STATES. (Eng.) Schulman, A. (Groote Schuur Hosp., Cape Town, South Africa). *J. Gastroenterol.* 68(2):167-170; 1977.

The case of a 44-yr-old Korean woman who presente in the United States with biliary ascariasis is reported. Several weeks after leaving Korea she presented with upper abdominal pain, light-colore diarrhea, nausea, vomiting, weight loss, and feve I.v. cholangiography and tomography revealed a co mon duct dilated to 17 mm and containing a long, vermiform filling defect, as well as a rounded defect just below it. Barium enema and upper gastr intestinal and small bowel examinations showed several similar vermiform defects in the upper jejunum and duodenum. A conventional 2-day regimen of p.o. peperazine was administered. A repeat i. cholangiogram 9 days after this treatment still showed the round defect in the common bile duct, but the vermiform filling defect had disappeared. Exploration and operative cholangiography were carried out during surgery for a gallstone and a stone in the common bile duct. No worms or oth abnormalities were found. *Ascaris lumbricoides* can usually be visualized by i.v. cholangiography because of the absence of obstructive jaundice an can therefore be specifically treated by nonsurgical methods. The radiographic appearance is diagnostic.

9245 LIVER AFFECTION ASSOCIATED WITH *Yersini* enterocolytica INFECTION. (Eng.) Saeb A. (Univ. Bergen Dept. Surgery, N-5016 Haukeland sjukehus, Bergen, Norway). *Acta Chir. Scand.* 14 (7/8):445-450; 1977.

A systematic screening of patients with acute abdominal disease of unknown origin revealed several cases with a positive antibody titer to *Yersinia enterocolytica*, coincident with elevate serum levels of aspartate amino transferase (ASA lactate dehydrogenase (LD), alkaline phosphatase

and bilirubin. Two cases are presented
tail. A woman born in 1916 had had abdom-
pain, fever, and diarrhea since childhood;
e 11 she had an erythema nodosum, and about
she developed epidemic hepatitis of brief dura-
Colics in the right side of the abdomen fol-
by meteorism, vomiting, and diarrhea lasting
ays began in 1949. Plain radiographs showed per-
al irritation and cholecystography was nega-
Right upper quadrant pain, diarrhea, fever,
y stools, a 5-kg weight loss, and swollen
ainful joints led to the admission during
the positive *Y. enterocolitica* antibody
was found. A liver biopsy revealed unchar-
istic liver changes, and splenomegaly was
osed scintigraphically. She was treated
sulfamethoxasol (1 g b.i.d.) and then ampi-
n (0.5 g t.i.d.). The antibody titer (to
terocolytica serogroup 3) remained positive
as stationary (1/160-1/320), and no pathogens
isolated from the stools. She was readmitted
77 for dark urine, clay-colored stools, and
-sided abdominal tenderness; i.v. chole-
graphy revealed no abnormalities. A woman
in 1900 had rheumatic fever in 1948 and
een twice in 1974 (for uncharacteristic dys-
a and for acute swelling of the left knee
). In 1976, she was admitted for dark urine
lay-colored stools; exploratory laparotomy
no gallbladder disease but an inflamed
. Biopsy revealed severe cholestasis, mod-
fatty degeneration, inflammation, and single-
necrosis. Prednisone therapy was insti-
for 2 weeks, withdrawn, and reinstituted
wing relapse. Tetracycline was given be-
seroreactions to *Y. enterocolytica* gave
s of 1/10 and then 1/320 over a 1-week per-
this titer continued to vary, improvement
ery slow, and electrophoresis showed a
ic, active process. No pathogens were isolated
fecal samples. It is suggested that chronic
cute forms of liver disease caused by *Y.
ocolytica* exist and may resemble chole-
tis in presentation.

METRONIDAZOLE IN CROHN'S DISEASE: A
DOUBLE BLIND CROSS-OVER CLINICAL TRIAL.
) Blichfeldt, P.; Blomhoff, J. P.; Myhre, E.;
, E. (Rikshospitalet, Oslo 1, Norway). *Scand.
stroenterol.* 13(1):123-127; 1978.

ble-blind crossover study of the value of
nidazole was carried out in 22 patients with
e Crohn's disease who were also being treated
salazosulfapyridin or prednisone. The patients received metronidazole (1,000 mg/day, p.o.) or placebo for 2 months. No statistically significant effect was observed in the overall clinical condition of the 20 patients who completed the trial, although the hemoglobin level rose and ESR fell significantly ($p<0.01$ and $p<0.05$, resp.) during metronidazole treatment. In the six patients in whom Crohn's disease involved only the colon, there was a striking improvement in symptoms, which included diarrhea and abdominal pain. Hemoglobin

rose and ESR fell in these patients during treatment. These results indicate that metronidazole is useful only in the treatment of Crohn's colitis.

9253 THE LONG-TERM PROPHYLACTIC EFFECT OF SALAZOSULPHAPYRIDINE (SALAZOPYRIN®) IN PRIMARILY RESECTED PATIENTS WITH CROHN'S DISEASE: A CONTROLLED DOUBLE-BLIND TRIAL.

(Eng.) Wenckert, A.; Kristensen, M.; Eklund, A. E.; Barany, F.; Jarnum, S.; Worning, H.; *et al.* (Herlev Univ. Hosp., DK 2730 Herlev, Denmark). *Scand. J. Gastroenterol.* 13(2):161-167; 1978.

A double-blind study of the possible prophylactic effect of salazosulphapyridine (SASP) in the treatment of Crohn's disease was carried out in 66 patients. Treatment with SASP (3 g/day, 32 patients) or placebo was started within 1 month following the patients' first surgical resection of diseased small or large bowel. The treatment period was 1 yr, and this was later prolonged to 18 months. Relapse-free patients were observed for 24 months. Using actuarial analysis, the four relapses that occurred in the patients treated with SASP and the nine in the placebo group after 18 months of treatment were calculated to correspond to cumulative relapse rates of 0.13 and 0.45, resp. ($0.10<p<0.15$). The results support the proposal that SASP is useful in preventing the recurrence of Crohn's disease following surgery. The need for large-scale trials is emphasized.

9254 URINARY OXALATE EXCRETION RELATED TO ILEOCOLIC SURGERY IN PATIENTS WITH CROHN'S DISEASE.

(Eng.) Andersson, H.; Filipsson, S.; Hulten, L. (Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *Scand. J. Gastroenterol.* 13(4): 465-469; 1978.

The effect of high oxalate and high fat diets on urinary oxalate excretion in 63 patients with Crohn's disease was studied before and after surgery and compared with results in 26 healthy controls. The urinary oxalate excretion was studied in relation to the length of the resected ileal segment in patients who had restorative and colectomy procedures and also in relation to the fecal excretion of fat and bile salts and to urinary excretion of vitamin B_{12} and calcium. Subjects received a standard hospital diet (about 75 g fat), with or without a high oxalate (800-900 mg) supplement from spinach and/or a high fat (150 g fat) supplement. Urinary oxalate excretion increased significantly when a high-oxalate diet was consumed by 15 patients with ileal or ileocolic disease ($p<0.001$) and in 23 patients with ileocolic resection or colectomy ($p<0.005$) compared with oxalate excretion on the standard diet. Controls on standard and high-oxalate diets had nearly identical oxalate excretion levels. Urinary oxalate excretion was significantly higher than control values in patients with ileocolic resections on both diets ($p<0.02$ and $p<0.001$, resp.) and in colectomized patients on the high-oxalate diet ($p<0.001$). A high-fat/high-oxalate diet increased urinary oxalate excretion in 25 patients with ileal resection ($p<0.01$) but not in 11 colectomized patients. In 35 patients subjected to ileal resection in conjunction with a limited colon resection (but not in the colectomized patients), the urinary oxalate excretion increased with the length of the resected ileal segment ($r=0.40$, $p<0.02$). A linear correlation ($r=0.50$, $p<0.005$) was obtained between the excretion of fat and of urinary oxalate in 33 patients with ileocolic resection (but none was observed in the colectomized patients). In 34 patients subjected to ileocolic resection, there was an exponential correlation between urinary oxalate and vitamin B_{12} excretion ($r=0.51$, $p<0.005$). No correlation between urinary oxalate excretion and bile salt malabsorption was found. In all patients, calcium excretion was low (5 mmol/24 hr for most patients), but no correlation with urinary oxalate excretion was found. A low-fat, low-oxalate, and high-calcium diet is recommended to prevent hyperoxaluria in patients after ileocolic resection, particularly where a substantial part of the colon is preserved.

9255 INVESTIGATION OF THE PATHOGENESIS AND ETIOLOGY OF CROHN'S DISEASE.

(Ger.) Raguse, T.; Bracker, H. P. (Abtlg. Chirurgie, Med. Fakultat d. RWTH, Goethestrasse 27/29, 51 Aachen, W. Germany). *Aktuel. Chir.* 12(5):317-326; 1977.

A study was undertaken to clarify the role of humoral and cellular competence of the immune syste in the etiology and pathogenesis of Crohn's disease (CD). Nine women and 11 men with severe, chronic recurring CD were studied. The levels of complemen factors C3 and C4 in the patients did not differ significantly from those of controls. IgG and IgA determinations were also within normal limits. IgM levels (222.1 ± 96.55 mg%), however, were significantly ($p<0.05$) above normal (102 ± 30 mg%). The sera of CD patients had a significant ($p<0.05$) inhibitory effect on stimulation in the mixed lymph cyte reaction (MLR). CD patients also had markedly increased lymphocyte counts. A marked increase in the absolute numbers of B cells existed, while the T cell count was decreased. Phytohemagglutinin stimulation showed a significant ($p<0.05$) anergy of the lymphocytes; in six patients, there was an extreme decrease in sensitivity to stimulation of the T lymphocytes. These findings indicate a distribution of the cellular immune system (in the sense of lymphocytic anergy) of undetermined cause. The inhibitory effect of CD sera in the MLR indicates blocking of the lymphocyte-specific cell function, which has been recognized in viral infections. Treatment of CD with immunosuppressive drugs is therefore questionable, while stimulation of the cellular immune system, as with Thymosin or Levamisole, is beneficial. Dietary supplements of amino acids are essential.

9256 PSEUDOPOLYPOID FORMS OF CROHN'S DISEASE.

(Fre.) Rouger, P.; Tubiana, J. M.; Douvin, D.; Chermet, J.; Monnier, J. P.; Malafosse, M *et al.* (Hopital Saint-Antoine, 184, rue du Faubour

int-Antoine, F 75571 Paris Cedex 12, France).
Radiol. Electrol. Med. Nucl. 58(12):807-810;
77.

ree cases are reported in men (ages 49, 34, and
yr, resp.) and one in a woman (age 26 yr) of
ohn's disease (regional ileitis) of a pseudo-
lypoid type. The inflammatory polyps were lo-
ted in the colon and the ileum and could be lo-
lized or diffuse. Actually, the polyps were the
sult of deep ulcerations of the intestinal mu-
sa surrounding healthy or only edematous mucosa
at appeared to project into the lumen of the in-
stinal tract. Diagnostically, pseudopolypoid
ohn's disease must be distinguished from ulcero-
morrhagic rectocolitis, familial intestinal poly-
sis, and lymphoid polyposis. X-ray studies alone
nnot be relied upon for accurate diagnosis, which
established by histological examination of bi-
sy material.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolis Digestive Diseases. This specialized information medium has been initiated to fill an existing great need the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal t Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers releva to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The nu and great diversity of publications in the area of gastroenterology makes it imperative that an appropriat service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators wi contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from th biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in th field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism, and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

August 1979

Dear Users:

It is with regret that the National Institute of Arthritis, Metabolism, and Digestive Diseases is discontinuing the publication of GASTROENTEROLOGY ABSTRACTS AND CITATIONS with Volume 12, Index Issue. With limited financial resources available to support research in the field of gastroenterology, it is necessary to make the maximum use of these limited funds.

When the publication GASTROENTEROLOGY ASBSTRACTS AND CITATIONS was initiated in 1967, it was both difficult and time consuming to locate relevant literature in the field. With this lack of resources, in order to move the field along, and as part of the support of research, the National Institute of Arthritis, Metabolism, and Digestive Diseases undertook publication of GASTROENTEROLOGY ABSTRACTS AND CITATIONS. Today there are more and different resources available for finding citations and abstracts of the literature in the field than there were a number of years ago, and there is no longer the void that prompted the development of GASTROENTEROLOGY ABSTRACTS AND CITATIONS.

In view of the limited resources of the Institute for research programs and the availability today of other literature sources, the Institute has decided to apply its resources maximally to the support of research activities. The last issue will be Volume 12, Index Issue.

Now that abstracts are available through MEDLINE (the National Library of Medicine's online computer retrieval of literature references) there is less need to publish an abstract journal. We shall be working with the National Library of Medicine, whose capability has greatly increased, in making the National Library of Medicine's vocabulary listing, Medical Subject Headings, more effective in the field of gastroenterology. We would welcome any comments and suggestions you may have in searching MEDLINE.

Yours truly,

Harold Roth

Harold P. Roth, M.D.
Associate Director for Digestive Diseases
and Nutrition
National Institute of Arthritis, Metabolism,
and Digestive Diseases
